INTEGRATION IN VALUED FIELDS

EHUD HRUSHOVSKI, DAVID KAZHDAN

Abstract. We develop a theory of integration over valued fields of residue characteristic zero. In particular we obtain new and base-field independent foundations for integration over local fields of large residue characteristic, extending results of Denef, Loeser, Cluckers. The method depends on an analysis of definable sets up to definable bijections. We obtain a precise description of the Grothendieck semigroup of such sets in terms of related groups over the residue field and value group. This yields new invariants of all definable bijections, as well as invariants of measure preserving bijections.

1. Introduction

Since Weil’s *Foundations*, algebraic varieties have been understood independently of a particular base field; thus an algebraic group $G$ exists prior to the abstract or topological groups of points $G(F)$, taken over various fields $F$. For Hecke algebras, or other geometric objects whose definition requires integration, no comparable viewpoint exists. One uses the topology and measure theory of each local field separately; since a field $F$ has measure zero from the point of view of any nontrivial finite extension, at the foundational level there is no direct connection between the objects obtained over different fields. The main thrust of this paper is the development of a theory of integration over valued fields, that is geometric in the sense of Weil. At present the theory covers local fields of residue characteristic zero or, in applications, large positive residue characteristic.

Our approach to integration continues a line traced by Kontsevich, Denef-Loeser, Loeser-Cluckers (cf. [7]). In integration over non-archimedean local fields there are two sources for the numerical values. The first is counting points of varieties over the residue field. Kontsevich explained that these numerical values can be replaced, with a gain of geometric information, by the isomorphism classes of the varieties themselves up to appropriate transformations, or more precisely by their classes in a a certain Grothendieck ring. This makes it possible to understand geometrically the changes in integrals upon unramified base change. In this aspect our approach is very similar. The main difference is a slight generalization of the the notion of variety over the residue field, that allows us to avoid what amounted to a choice of uniformizer in the previous theory.

The second source of the numbers is the piecewise linear geometry of the value group. We geometrize this ingredient too, obtaining a theory of integration taking values in an entirely geometric ring, a tensor product of a Grothendieck ring of generalized varieties over the residue field, and a Grothendieck ring of piecewise linear varieties over the value group.

Viewed in this way, the integral is an invariant of measure preserving definable bijections. We actually find all such invariants. In addition we consider and determine all possible invariants of definable bijections; we obtain in particular two Euler characteristics on definable sets, with values in the Grothendieck group of generalized varieties over the residue field.

At the level of foundations, until an additive character is introduced, we are able to work with Grothendieck semigroups rather than with classes in Grothendieck groups.

1.1. The logical setting. Let $L$ be a valued field, with valuation ring $\mathcal{O}_L$. $\mathcal{M}$ denotes the maximal ideal. We let $\text{VF}^n(L) = L^n$. The notation $\text{VF}^n$ is analogous to the symbol $\mathbb{A}^n$ of algebraic geometry, denoting affine $n$-space. Let $\text{RV}^m(L) = L^*/(1 + \mathcal{M})$, $\Gamma(L) = L^*/\mathcal{O}_L^*$, $k(L) = \mathcal{O}_L/\mathcal{M}_L$. Let $\text{rv} : \text{VF} \to \text{RV}$ and $\text{val} : \text{VF} \to \Gamma$ be the natural maps. The natural map $\text{RV} \to \Gamma$ is denoted $\text{val}_\gamma$. The exact sequence

$$0 \to k^* \to \text{RV} \to \Gamma \to 0$$

shows that RV is, at first approximation, just a way to wrap together the residue field and value group.

We consider expressions of the form $h(x) = 0$ and $\text{val}(x) \geq \text{val}(y)$ where $f, g, h \in L[X], X = (X_1, \ldots, X_n)$. A semi-algebraic formula is a finite Boolean combination of such basic expressions. A semi-algebraic formula $\phi$ clearly defines a subset $D(L)$ of $\text{VF}^m(L)$. Moreover if $f, g, h \in L_0[X]$, we obtain a functor $L \mapsto D(L)$ from valued field extensions of $L_0$ to sets. We will later describe more general definable sets; but for the time being take a definable subset of $\text{VF}^n$ to be a functor $D = D_\phi$ of this form.

An intrinsic description of definable subsets of $\text{RV}^m$ is given in §2.1. In particular, definable of $(k^*)^m$ coincide with constructible sets in the usual Zariski sense; while modulo $(k^*)^m$, a
definable set is a piecewise linear subset of $\Gamma^n$. The structure of arbitrary definable subsets of $RV^n$ is analyzed in §3.3.

The advantages of this approach are identical to the benefits in algebraic geometry of working with arbitrary algebraically closed fields, over arbitrary base fields. One can use Galois theory to describe rational points over subfields. Since function fields are treated on the same footing, one has a mechanism to inductively reduce higher dimensional geometry to questions in dimension one, and often in fact to dimension zero (as in algebraic geometry, statements about fields, applied to generic points, can imply birational statements about varieties.)

1.2. Model theory. Since topological tools are no longer available, it is necessary to define notions such as dimension in a different way. The basic framework comes from [15]; we recall and develop it further in §2 and §4. It is in many respects analogous to the $\omega$-minimal framework of [36], that has become well-accepted in real algebraic geometry.

In addition, whereas in geometry all varieties are made as it were of the same material, here a number of rather different types of objects co-exist, and the interaction between them must be clarified. In particular, the residue field and the value group are orthogonal in a sense that will be defined below; definable subsets of one can never be isomorphic to subsets of the other, unless both are finite. This orthogonality has an effect on definable subsets of $VF^n$ in general; for example, closed disks behave very differently from open ones. Here we follow and further develop [16].

Note that the set of rational points of closed and open disks over discrete valuation rings, for instance, cannot be distinguished; as in rigid geometry, the geometric setting is required to make sense of the notions. Nevertheless they have immediate consequences to local fields. As an example, we define the notion of a definable distribution; these are defined as a function on the space of polydisks with certain properties. Making use of model theoretic properties of the space of polydisks, we show that any definable distribution agrees outside a proper subvariety with one obtained by integrating a function. This is valid over any valued field of sufficiently large residue characteristic. In particular for large $p$, the $p$-adic Fourier transform of a rational polynomial is a locally constant function away from an exceptional subvariety, in the usual sense (Corollary 11.10.) The analogue for $\mathbb{R}$ and $\mathbb{C}$ was proved by Bernstein using D-modules. For an individual $\mathbb{Q}_p$, the same result can be shown using Denef integration and a similar analysis of definable sets over $\mathbb{Q}_p$. These results were obtained independently by Cluckers and Loeser, cf. [8].

1.3. More general definable sets. Throughout the paper we discuss not semi-algebraic sets, but definable subsets of a theory with the requisite geometric properties (called $V$-minimality.) This includes also the rigid analytic structures of [23]. The adjective “geometrically” can be taken to mean here: in the sense of the $V$-minimal theory.

While we work geometrically throughout the paper, the isomorphisms we obtain are canonical and so specialize to rational points over substructures. Thus a posteriori our results apply to definable sets over any Hensel field of large residue characteristic. See §12.

For model theorists, this systematic use of of algebraically closed valued fields to apply to other Hensel fields is only beginning to be familiar. As an illustration, see Proposition 12.9, where it is shown that after a little analysis of definable sets over algebraically closed valued fields, quantifier elimination for Henselian fields of residue characteristic zero becomes a consequence of Robinson’s earlier quantifier elimination in the algebraically closed case.

A third kind of generalization is an $\alpha$-posteriori expansion of the language in the $RV$ sort. Such an expansion involves loss of information in the integration theory, but is sometimes useful. For instance one may want to use the Denef-Pas language, splitting the exact sequence into a
product of residue field and value group. Another example occurs in Theorem 12.5 where it is explained, given a valued field whose residue field is also a valued field, what happens when one integrates twice. To discuss this, the residue field is expanded so as to become itself a valued field.

1.4. Generalized algebraic varieties. We now describe the basic ingredients in more detail.

Let $L_0$ be a valued field with residue field $k_0$ and value group $A$. For each point $\gamma \in \mathbb{Q} \otimes A$ we have one-dimensional $k$-vector space

$$V_\gamma = \{0\} \cup \{x \in K : \text{val}(x) = \gamma\}/(1 + \mathcal{M})$$

As discussed above, $V_\gamma$ should be viewed as a functor $L \mapsto V_\gamma(L)$ on valued field extensions $L$ of $L_0$, giving a vector space over the residue field functor. If $\gamma - \gamma' \in A$ then $V_\gamma, V_\gamma'$ are definably isomorphic, so one essentially has $V_\gamma$ for $\gamma \in (\mathbb{Q} \otimes A)/A$.

Fix $\bar{\gamma} = (\gamma_1, \ldots, \gamma_n)$, and $V_1 = V_{\gamma_1}, V_\gamma = \Pi_i V_{\gamma_i}$. A $\bar{\gamma}$-polynomial is an polynomial $H(X) = \sum a_\nu X^\nu$ with $\text{val}_\nu(a_\nu) + \sum_i \nu(i)\gamma_i = 0$ for each nonzero term $a_\nu X^\nu$. The coefficients $a_\nu$ are described in §5.5.1; for the purposes of the introduction, and of Theorem 1.3 below, it suffices to think of integer coefficients. Such a polynomial clearly defines a function $H : V_\bar{\gamma} \to k$. In particular one has the set of zeroes $Z(H)$. The generalized residue structure $\text{RES}_{L_0}$ is the residue field, together with the collection of one-dimensional vector spaces $V_\gamma (\gamma \in \mathbb{Q} \otimes A)$ over it, and the functions $H : V_\gamma \to k$ associated to each $\bar{\gamma}$-polynomial.

The intersection $W$ of finitely many zero sets $Z(H)$ is called a generalized algebraic variety over the residue field. Given a valued field extensions $L$ of $L_0$, we have the set of points $W(L) \subseteq V_\bar{\gamma}(L)$. When $L$ is a local field, $W(L)$ is finite.

We will systematically use the Grothendieck group of generalized varieties residue field, rather than the usual Grothendieck group of varieties. They are fundamentally of a similar nature: base change to an algebraically closed value field makes them isomorphic. But the generalized residue field makes it possible to to see canonically objects that are only visible after base change in the usual approach. One application is Theorem 1.3 below.

$K_1 \text{RES}_{L_0}[n]$ denotes the Grothendieck group of generalized varieties of dimension $\leq n$; in the paper we will omit $L_0$ from the notation.

1.5. Rational polyhedra over ordered Abelian groups. Let $A$ be an ordered Abelian group. A rational polyhedron $\Delta$ over $A$ is given by an expression

$$\Delta = \{x : Mx \geq b\}$$

with $x = (x_1, \ldots, x_n)$, $M$ a $k \times n$ - matrix with rational coefficients, and $b \in A^k$. We view this as a functor $B \mapsto \Delta(B)$ on ordered Abelian group extensions $B$ of $A$. This functor is already determined by its value at $B = \mathbb{Q} \otimes A$. In particular when $A \leq \mathbb{Q}$, $\Delta$ is an ordinary rational polyhedron.

$K_1 \Gamma_A[n]$ is the semigroup generated by such polyhedra, up to piecewise $G_{L_n}(\mathbb{Z})$-transformations and $\Lambda$-translations; see §9. When $A$ is fixed it is omitted from the notation.

In our applications, $A$ will be the value group of a valued field $L_0$. If $B$ is the value group of a valued field extension $L$, write $\Delta(L)$ for $\Delta(B)$.

1.6. The Grothendieck semiring of definable sets. Fix a base field $L_0$. The word “definable” will mean: $T_{L_0}$-definable, with $T$ a fixed V-minimal theory. To have an example in mind one can read “semi-algebraic over $L_0$” in place of “definable”.

Let $\text{VF}[n]$ be the category of definable subsets $X$ of $n$-dimensional algebraic varieties over $L_0$; a morphism $X \to X'$ is a definable bijection $X \to X'$ (see Definition 3.65 for equivalent
definitions.) $K_+VF[n]$ denotes the Grothendieck semi-group, i.e., the set of isomorphism classes of $VF[n]$ with the disjoint sum operation. $[X]$ denotes the class of $X$ in the Grothendieck semi-group.

We explain how an isomorphism class of $VF[n]$ is determined precisely by isomorphism classes of generalized algebraic varieties, and rational polyhedra, whose dimensions add up to $n$.

If $X \subseteq \text{RES}^m$ and $f : X \to \text{RES}^n$ is a finite-to-one map, let

$$L(X, f) = \text{VF}^n \times_{\pi, f} X = \{(v_1, \ldots, v_n, x) : v_i \in \text{VF}, x \in X, rv(v_i) = f_i(x)\}$$

The $\text{VF}[n]$-isomorphism class $[L(X, f)]$ does not depend on $f$, and is also denoted $[LX]$.

When $S$ is a smooth scheme over $0$, $X$ a definable subset of $S(k)$, $\pi : S(0) \to S(k)$ the natural reduction map, we have $[LX] = [\pi^{-1}X]$.

We let $\text{RES}[n]$ be the category of pairs $(X, f)$ as above; a morphism $(X, f) \to (X', f')$ is just a definable bijection $X \to X'$. Let $K_+\text{RES}[s]$ be the direct sum of the Grothendieck semigroups $K_+\text{RES}[n]$.

On the other hand, we have already defined $K_+\Gamma[n]$. Let $K_+\Gamma[s]$ be the direct sum of the $K_+\Gamma[n]$. An element of $K_+\Gamma[n]$ is represented by a definable $X \subseteq \Gamma[n]$. Let $LX = \text{val}^{-1}(X)$, $L[X] = [LX]$.

It is shown in Proposition 10.2 that the Grothendieck semiring of $\text{RV}$ is the tensor product $K_+\text{RES}[s] \otimes K_+\Gamma[s]$ over the semiring $K_+\Gamma^f$ of classes of finite subsets of $\Gamma$; see §9.

Note that $L([1]) = L([1]) + L([0, \infty])$, where $[1] \in K_+\text{RES}[1]$, $[1] \in K_+\text{RES}[0]$ are the classes of the singleton set 1, and $[0, \infty]$ is the class in $K_+\Gamma[1]$ of the semi-infinite segment $(0, \infty)$. Indeed $L([1])$ is the unit open ball around 1, $L([1])$ is the point $\{1\}$, while $L([0, \infty])$ is the unit open ball around 0, isomorphic by a shift to the unit open ball around 1. This is the only relation that cannot be understood in terms of the Grothendieck semi-ring of $\text{RV}$; it will be seen to correspond to the analytic summation of geometric series in the Denef theory. Let $I_{sp}$ be the congruence on the ring $K_+\text{RES}[s] \otimes K_+\Gamma[s]$ generated by: $[1] \sim [1] + ([0, \infty])$. The following theorem summarizes the relation between definable sets in $\text{VF}$ and in $\text{RV}$; it follows from Theorem 8.4 together with Proposition 10.2 in the text.

**Theorem 1.1.** $L$ induces an surjective homomorphism of filtered semirings

$$K_+\text{RES}[s] \otimes K_+\Gamma[s] \to K_+(\text{VF})$$

The kernel is precisely the congruence $I_{sp}$.

The inverse isomorphism $K_+(\text{VF}) \to K_+\text{RES}[s] \otimes K_+\Gamma[s]/I_{sp}$ can be viewed as a kind of Euler characteristic, respecting products and disjoint sums, and functorial in various other ways.

The values of this Euler characteristic are themselves geometric objects, both on the algebraic-geometry side (RES) and the combinatorial-analytic side ($\Gamma$). This is valuable for some purposes; in particular it becomes clear that the isomorphism is compatible with taking rational points over Henselian subfields (cf. Proposition 12.6)

For other applications, however, it would be useful to obtain more manageable numerical invariants; for this purpose one needs to analyze the structure of $K_+\Gamma[*]$. We do not fully do this here, but using a number of homomorphisms on $K_+\Gamma[*]$ we obtain a number of invariants. In particular using the $\mathbb{Z}$-valued Euler characteristics on $K\Gamma[*]$ (cf. §9 and [26], [20]), we obtain two homomorphisms on $K_+VF[n]$ essentially to $K(\text{RES}[n])$. The reason there are two rather than one has to do with Poincaré duality, see Theorem 10.5.

For instance, when $F$ is a field of characteristic 0 we obtain an invariant of rigid analytic varieties over $F((t))$, with values in the Grothendieck ring $K(\text{Var}_F)$ of algebraic varieties over $F$; and another in $K(\text{Var}_F)[[\widehat{A}_1]]^{-1}$ (Proposition 10.8). It is instructive to compare this with the
invariant of [25], with values in $K(\text{RES}[\omega])/[G_m]$. ¹ Since any two closed balls are isomorphic, via additive translation and multiplicative contractions, all closed balls must have the same invariant. Working with a discrete value group tends to force $[G_m] = 0$, since it appears that a closed ball $B_0$ of valuation radius 0 equals $G_m$ times a closed ball $B_1$ of valuation radius 1. Since our technology is based on divisible value groups, the “equation” $[B_0] = [B_1][G_m]$ is replaced for us by $[B_0] = [B_0][G_m]$, where $B_0$ is the open ball of valuation radius 0. Though $B_1$ and $B_0$ have the same $F((t))$-rational points, they are geometrically distinct (cf. Lemma 3.46) and so no collapse takes place.

See also subsections 12.6.1 and 12.6.2 for two previously known cases.

By such Euler characteristic methods we can prove a statement purely concerning algebraic varieties, partially answering a question of Gromov and Kontsevich ([13], p. 121.). In particular, two elliptic curves with isomorphic complements in projective space were previously known to be isogenous, by zeta function methods; we show that they are isomorphic. This also follows from [22]; the method there requires strong forms of resolution of singularities. See Theorem 13.1.

1.7. Integration of forms up to absolute value. Over local fields, data for integration consists of a triple $(X, V, \omega)$, with $X$ a definable subset of a smooth variety $V$, and $\omega$ a volume form on $V$. We are interested in an integral of the form $\int_X [\omega]$, so that multiplication of $\omega$ by a function with norm one does not count as a change, nor does removing a subvariety of $V$ of smaller dimension. Using an equivalent description of $\text{VF}[n]$, where the objects come with a distinguished finite-to-one map into affine space, we can represent an integrand as a pair $(X, \omega)$ with $X \in \text{Ob} \text{VF}[n]$ and $\omega$ a function on $X$ into $\Gamma$. Isomorphisms are essential bijections, preserving the form up to a function of norm 1. See Definition 8.10 for a precise definition of this category, the category $\mu_1 \text{VF}[n]$.

Integration is intended to be an invariant of isomorphisms in this category. Thus we can find the integral if we determine all invariants. We do this in complete analogy with Theorem 1.1.

For $n \geq 0$ let $\Gamma[n]$ be the category whose objects are finite unions of rational polyhedra over the group $A$ of definable points of $\Gamma$. A morphism $f : X \to Y$ of $\Gamma[n]$ is a bijection such that for some partition $X = \bigcup_{i=1}^t X_i$ into rational polyhedra, $f[X_i]$ is given by an element of $GL_n(\mathbb{Z}) \ltimes A^n$. Let $\mu_1 \Gamma[n]$ be the category of pairs $(X, \omega)$, with $X$ an object of $\Gamma[n]$, and $\omega : X \to \Gamma$ a piecewise affine map. A morphism $f : (X, \omega) \to (X', \omega')$ is a morphism $f : X \to X'$ of $\Gamma[n]$ such that $\sum_{i=1}^t x_i + \omega(x) = \sum_{i=1}^t x'_i + \omega'(x')$ whenever $(x_1, \ldots, x_n) = f(x_1, \ldots, x_n)$. Given $(X, \omega) \in \text{Ob} \mu_\Gamma[n]$, define $LX$ as above, and adjoint the pullback of $\omega$ to obtain an object of $\mu_1 \text{VF}[n]$. This gives a homomorphism $K_+ \mu_\Gamma[n] \to K_+ \mu_1 \text{VF}[n]$.

**Theorem 1.2.** Let $L$ induce an surjective homomorphism of filtered semirings $K_+ \text{RES}[\ast] \otimes_{K_+ \mu \Gamma[\ast]} K_+ \mu_1 \Gamma[\ast] \to K_+ (\mu_1 \text{VF})[\ast]$.

The kernel is generated by the relations $p \otimes 1 = 1 \otimes ([\text{val}_p(p), \infty)]$ and $1 \otimes a = \text{val}_p^{-1}(a) \otimes 1$.

In the statement of the theorem, $p$ ranges over definable points of RES (actually one value suffices), and $a$ ranges over definable points of $\Gamma$.

This can also be written as $(K_+ \text{RES}[\ast] \otimes_{K_+ (\mu_1 \Gamma^\text{fin})} K_+ \mu_1 \Gamma[\ast]) / \mu_{\text{IP}} \simeq K_+(\mu_1 \text{VF})[\ast]$, where $K_+(\mu_1 \Gamma^\text{fin})$ is the subsemiring of subsets of $\mu_1 \Gamma$ with finite support, and $\mu_{\text{IP}}$ is a semiring congruence defined similarly to $\mu_{\text{IP}}$. The base of the tensor leads to the identification of a point of $\Gamma$ with a coset of $k^\ast$ in RES, while $\mu_{\text{IP}}$ identifies a point of RES with an infinite interval of $\Gamma$. The inverse isomorphism can be viewed as an integral.

¹The setting is somewhat different: Loeser-Sebag can handle positive characteristic too, but assume smoothness.
We introduce neither additive nor multiplicative inverses in $\mathbb{K}_r \text{RES}[x]$ formally, so that the target of integration is completely geometric.

We proceed to give an application of the first part of the theorem (the surjectivity) in terms of ordinary p-adic integration.

1.8. Integrals over local fields: uniformity over ramified extensions. Let $L$ be a local field, finite extension of $\mathbb{Q}_p$ or $\mathbb{F}_p((t))$. We normalize the Haar measure $\mu$ in such a way that the maximal ideal has measure 1, the norm by $|a| = \mu\{x : |x| < |a|\}$. Let $\text{RES}_L$ be the generalized residue field, and $\Gamma_L$ be the value group. We assume $\mathbb{Q}_p$ or $\mathbb{F}_p((t))$ have value group $\mathbb{Z}$, and identify $\Gamma_L$ with a subgroup of $\mathbb{Q}$.

Given $c = (c_1, \ldots, c_k) \in L^k$ and $s = (s_1, \ldots, s_k) \in \mathbb{R}^k$ with $s_i \geq 1$, let $|c|^s = \Pi_{i=1}^k |c_i|^{s_i}$.

Let $\lambda$ be a multiplicative character $\mathbb{R}^n \to \mathbb{R}^*$. Define:

$$ev_\lambda(\Delta(B)) = \sum_{b \in \Delta(B)} \lambda(b)$$

provided this sum is absolutely convergent. Given linear functions $h_0, \ldots, h_k$ on $\mathbb{R}^n$ and $s_1, \ldots, s_k \in \mathbb{R}$, let $ev_{h,s,Q} = ev_\lambda$ where $\lambda(x) = Q^{h_0(x)} \prod_{i=1}^k s_i h_i(x)$

**Theorem 1.3.** Fix $n, d, k \in \mathbb{N}$. Let $p$ be a large prime compared to $n, d, k$, and let $f \in \mathbb{Q}_p[X_1, \ldots, X_n]^k$ have degrees $\leq d$. Then there exist finitely many generalized varieties $X_i$ over $\text{RES}(\mathbb{Q}_p)$, rational polyhedra $\Delta_i$, $\gamma(i) \in \mathbb{Q}^{=0}$, $n_i \in \mathbb{N}$, and linear functions $h_i^0, \ldots, h_i^k$ with rational coefficients, such that for any finite extension $L$ of $\mathbb{Q}_p$ with residue field $\text{GF}(q)$ and $\text{val}(L^*) = (1/r)\mathbb{Z}$, $\text{val}(p) = 1$, and any $s \in \mathbb{R}_{>1}^k$,

$$\int_{O_L^{\mathbb{Q}}} \lfloor f \rfloor^s = \sum_{i} q^{-n_i} \gamma(i) |X_i(L)| ev_{h_i^0, \ldots, h_i^k, q^s} (\Delta_i(L))$$

Note:
1) $\Delta_i(L)$ depends only on the ramification degree $r$ of $L$ over $\mathbb{Q}_p$.
2) The formula is a sum of non-negative terms.
3) $ev_{h,s,q^r} (\Delta_i ((1/r)\mathbb{Z}))$ can be written in closed form as a rational function of $q^r$. This follows from Denef, who shows it for more general sets $\Delta_i$ definable in Presburger arithmetic; such analytic summation is an essential component of his integration theory. Since it plays no role in our approach we leave the statement in geometric form.
4) The generalized varieties $X_i$ and polyhedra $\Delta_i$ are simple functions of the coefficients $f$. Here we wish to emphasize not this, but the uniformity of the expression over ramified extensions of $\mathbb{Q}_p$.

The proof follows Proposition 10.10 (it uses only the easy surjectivity in this proposition, and Proposition 4.5.)

1.9. Bounded and unbounded sets. The isomorphism of semirings of Theorem 1.2 obviously induces an isomorphism of rings. However introducing additive inverses loses information on the $\Gamma$ side; the class of the interval $[0, 1)$ becomes 0, since $[0, \infty)$ and $[1, \infty)$ are isomorphic. The classical remedy is to cut down to bounded sets before groupifying. This presents no difficulty, since the isomorphism respects boundedness.

In higher dimensional local fields, stronger notions of boundedness may be useful, such as those introduced by Fenenko. Since these questions are not entangled with the theory of integration, and can be handled a posteriori, we will deal with them in a sequel.

Here we mention only that even if one insists on integrating all definable integrands, with no boundedness condition, into a ring, some but not all information is lost. This is due to the existence of Euler characteristics on $\Gamma$, and thus again to the fact that we work geometrically,
with divisible groups, even if the base field has a discrete group. We will see (Lemma 9.12) that $K_+(\mu \Gamma[n])$ can be identified with the group of definable functions $\Gamma \to K_+(\Gamma[n])$. Applying an appropriate Euler characteristic reduces to the group of piecewise constant functions on $\Gamma$ into $\mathbb{Z}$. Reconstructing with RES we obtain a consistent definition of an integral on unbounded integrands, compatible with measure preserving maps, sums and products, with values in $K(\text{RES})[A]/[\mathcal{A}_i]K(\text{RES})[A]$, where $A$ is the group of definable points of $\Gamma$, and $[\mathcal{A}_i]$ is the class of the affine line. See Theorem 10.11.

1.10. finer volumes. We also consider a finer category of definable sets with RV-volume forms. This means that a volume form $\omega$ is identified with $g \omega$ only when $g - 1 \in M$; $\text{val}(g) = 0$ does not suffice. We obtain an integral whose values themselves are definable sets with volume forms; in particular including algebraic varieties with volume forms over the residue field.

**Theorem 1.4.** $L$ induces an surjective homomorphism of graded semirings

$$K_+ \mu \text{RV}[\ast] \to K_+ (\mu \text{VF})[\ast]$$

The kernel is precisely the congruence $\mu \Lambda_{sp}$.

$\mu \text{RV}$ is the category of definable subsets of $\mu \text{RV}^*$ enriched with volume forms; see Definition 8.13. Again, an isomorphism is induced in the opposite direction, that can be viewed as a motivic integral

$$\int : K_+(\mu \text{VF})[\ast] \to K_+ \mu \text{RV}[\ast]/\mu \Lambda_{sp}$$

This allows an iteration of the integration theory, either with an integral of the same nature if the residue field is a valued field, or with a different kind of integral if for instance the residue field is $\mathbb{R}$.

1.11. Hopes. We mention three. Until now, a deep obstacle existed to extending Denef’s theory to positive characteristic; namely the theory was based on quantifier elimination for Hensel fields of residue characteristic 0, or for finitely ramified extensions of $\mathbb{Q}_p$, and it is known that no similar quantifier elimination is possible for $\mathbb{F}_p((t))$, if any is. On the other hand Robinson’s quantifier elimination is perfectly valid in positive characteristic. This raises hopes of progress in this direction, though other obstacles remain.

It is natural to think that the theory can be applied to higher dimensional local fields; we will consider this in a sequel.

Another important target is asymptotic integration over $\mathbb{R}$. Nonstandard extensions of $\mathbb{R}$ admit natural valued field structures. This is the basis of Robinson’s nonstandard analysis. These valued fields have divisible value groups, and so previous theories of definable integration do not apply. The theory of this paper applies however, and we expect that it will yield connections between $p$-adic integration and asymptotics of real integrals.

1.12. Course of the paper. After recalling some basic model theory in §2, we proceed in §3 to V-minimal theories.

In §4 we show that any definable subset of $\text{VF}^n$ admits a constructible bijection with some $\mathcal{L}(X, f)$. In fact only a very limited class bijections is needed; a typical one has the form: $(x_1, x_2) \mapsto (x_1, x_2 + f(x_1, x_2))$, so it is clearly measure preserving. The proof is simple and brief, and uses only a little of the preceding material. We note here that for many applications this statement is already sufficient; in particular it suffices to give the surjectivity in Theorems 1.1 and 1.2, and hence the application Theorem 1.3.

In §5 we return to the geometry of V-minimal structures, developing a theory of differentiation. We show the compatibility between differentiation in RV and in VF. This is needed for Theorem 1.4. Differentiation in VF involves much finer scales than in RV; in effect RV can
only see distances measured by valuation 0, while the derivative in VF involves distances of arbitrarily large valuation. The proof uses a continuity argument on scales. It fails in positive characteristic, in its present form.

§6 is devoted to showing that L yields a well-defined map $K_+(RV) \to K_+(VF)$; in other words not only objects, but also isomorphism can be lifted.

Sections §7 and §8 investigate the kernel of L in Theorem 1.1. This is the most technical part of the paper, and we have not been able to give a proof as functorial as we would have liked. See Question 7.9.

In §9 we study the piecewise linear Grothendieck group; see the introduction to this section.

§10 decomposes the Grothendieck group of RV into the components RES and $\Gamma$, used throughout this introduction.

§11 introduces an additive character, and hence the Fourier transform. The isomorphism of volumes given by Theorem 1.4 suffices for this extension; it is not necessary to redo the theory from scratch, but merely to follow through the functoriality.

§12 contains the extension to definable sets over Hensel fields mentioned above, and §13 the application to the Grothendieck group of varieties.

Thanks to Avi Tatarsky and Moshe Kaminsky, and to Lou Van den Dries, Clifton Ealy, and Jana Maríková, for useful comments and corrections.

2. First order theories

The bulk of this paper uses no deep results from logic, beyond Robinson’s quantifier elimination the theory of algebraically closed valued fields ([32]). However, it is imbued with a model theoretic viewpoint. We will not explain the most basic notions of logic: language, theory, model. Let us just mention that a language consists of basic relation and function symbol, and formulas are built out of these, using symbols for Boolean operations and quantifiers; cf. e.g. [11] or [19], or the first section of [9]); but we attempt in this section to bridge the gap between these and the model-theoretic language used in the paper.

A language $L$ consists of a family of “sorts” $S_i$, a collection of variables ranging over each sort, a set of relation symbols $R_j$, each intended to denote a subset of a finite product of sorts, and a set of function symbols $F_k$ intended to denote functions from a given finite product of sorts to a given sort. From these, and the logical symbols $\&, \neg, \forall, \exists$ one forms formulas. A sentence is a formula with no free variables (cf. [11].) A theory $T$ is a set of sentences of $L$. A theory is called complete if for every sentence $\phi$ of $L$, either $\phi$ or its negation $\neg \phi$ is in $T$.

A universe $M$ for the language $L$ consists, by definition, of a set $S(M)$ for each sort $S$ of $L$. An $L$-structure consists of such a universe, together with an interpretation of each relation and function symbol of $L$. One can define the truth value of a sentence in a structure $M$; more generally, if $\phi(x_1, \ldots, x_n)$ is a formula, with $x_i$ a variable of sort $S_i$, then one defines the interpretation $\phi(M)$ of $\phi$ in $M$, as the set of all $d \in S_1(M) \times \ldots \times S_n(M)$ of which $\phi$ is true. If every sentence in $T$ is true in $M$, one says that $M$ is a model of $T$ ($M \models T$). The fundamental theorem here is a consequence of Gödel’s completeness theorem called the compactness theorem: a theory $T$ has a model if every finite subset of $T$ has a model.

The language $L_{ring}$ of rings, for example, has one sort, three function symbols $+, \cdot, 0, 1$; any ring is an $L_{ring}$-structure; one can obviously write down a theory $T_{fields}$ in this language whose models are precisely the fields.

2.1. Basic examples of theories. We will work with a number of theories associated with valued fields.
(1) ACF, the theory of algebraically closed fields. The language is the language of rings \{+,\cdot,\neg,0,1\}, mentioned earlier. The theory states that the model is a field, and for each \(n\), that every monic polynomial of degree \(n\) has a root. For instance for \(n = 2\):

\[(\forall u_1)(\exists x)(x^2 + u_1 x + u_0 = 0)\]

ACF(0) includes in addition the sentences: \(1 + 1 \neq 0, 1 + 1 + 1 \neq 0, \ldots\). This theory is complete (Tarski-Chevalley.) It will arise as the theory of the residue field of our valued fields.

(2) Divisible ordered Abelian groups (DOAG). The language consists of a single sort, a binary relation symbol \(<\), a binary function symbol \(+\), a unary function symbol \(\neg\) and a constant symbol \(0\). The theory states that a model is an ordered Abelian group. In addition axioms asserting divisibility by \(n\) for each \(n\), for instance: \((\forall x)(\exists y)(y + y = x)\).

This is the theory of the value group of a model of ACVF.

(3) The RV sort. (Extension of (2) by (1)). The language has one official sort, denoted RV, and includes: Abelian group operations \(+/\) on RV, a unary predicate \(k^*\) for a subgroup, and an operation \(+\colon k^2 \to k\), where \(k\) is \(k^*\) augmented by a constant \(0\). Finally, there is a partial ordering; the theory states that \(k^*\) is the equivalence class of \(1\); that \(\leq\) is a total ordering on \(k^*-\)cosets, making RV/\(k^*\) = \(\Gamma\) a divisible ordered Abelian group, and that \((k, +, \cdot)\) is an algebraically closed field. (We thus have an exact sequence \(0 \to k^* \to RV \to \Gamma \to 0\), but we treat \(\Gamma\) as an imaginary sort.) This theory TRV is complete too.

We will sometimes view RV as an autonomous structure; but it will arise from an algebraically closed valued field, as in (5) below.

(4) Let \(M \models TRV\), and let \(A\) be a subgroup of \(\Gamma(M)\). Within TRV\(_A\) we see an interpretation of ACF, namely the algebraically closed field \(k\). In addition for each \(a \in A\) we have a 1-dimensional \(k\)-space, the fiber of RV lying over \(\Gamma\) augmented by \(0\). Collectively the field \(k\) with this collection of vector spaces will be denoted RES.

(5) ACVF, the theory of algebraically closed valued fields. According to Robinson, the completions, denoted ACVF\(_q,p\), are obtained by specifying the characteristic \(q\) and residue characteristic \(p\). We will be concerned with ACVF\((0,0)\) in this paper. However since any sentence of ACVF\((0,0)\) lies in ACVF\((0,p)\) for almost all primes \(p\), the results will a posteriori apply also to valued fields of characteristic zero and large residue characteristic.

We will take ACVF\((0,0)\) to have two sorts, VF and RV = VF*/\((1+M)\). The language includes the language of rings (1) on the VF sort, the language (3) on the RV sort, and a function symbol \(rv\) for a function VF*/RV. Denote \(rv^{-1}(RV \geq 0) = 0, rv^{-1}(0) = M\).

The theory states that VF is a valued field, with valuation ring \(0\) and maximal ideal \(M\); that \(rv : VF^* \to RV\) is a surjective group homomorphism, and the restriction to \(0\) (augmented by \(0 \to 0\)) is a surjective ring homomorphism.

The structure ACVF\(_A\) induces on \(\Gamma\) is of a uniquely divisible Abelian group, with constants for the elements of \(\Gamma(A)\). Thus every definable subset of \(\Gamma\) is a finite union of points and open intervals (possibly infinite.)

(6) Rigid analytic expansions (Lipschitz) The theory ACVF\(_R\) of algebraically closed valued fields expanded by a family \(R\) of analytic functions. See [23] and [24]. Our theory of definable sets will be carried out axiomatically, and are thus also valid for these rigid analytic expansions.

A definable set \(D\) is not really a set, but a functor from the category of models of \(T\) to the category of sets of the form \(M \mapsto \phi(M)\), where \(\phi\) is a formula of \(L\). Model theorists do not
really distinguish between the definable sets $D$ and the formula $\phi$ defining it; we will usually refer to definable sets rather than to formulas. If $R \subseteq D \times D'$ and for any model $M \models T$, $R(M)$ is the graph of a function $D(M) \to D(M')$, we say $R$ is a definable function of $T$. Similarly we say $D$ is finite if $D(M)$ is finite for any $M \models T$, etc. It follows from the compactness theorem that if $D$ is finite, then for some integer $m$ we have $|D(M)| \leq m$ for any $M \models T$. We sometimes write $S^*$ to denote $S^n$ for some unspecified $n$.

By a map between $L$-structures $A, B$ we mean a family $f = (f_S)$ indexed by the sorts of $L$, with $f_S : S(A) \to S(B)$; one extends $f$ to products of sorts by setting $f((x_1, \ldots, x_n)) = (f(x_1), \ldots, f(x_n))$. $f$ is an embedding of structures if $f^{-1} R(B) = R(A)$ for any atomic formula $R$ of $L$. Taking $R$ to be the equality relation, this includes in particular the statement that each $f_S$ is injective.

On occasion we will use $\infty$-definable sets. An $\infty$-definable set is a functor of the form $M \mapsto \cap \mathcal{D}$, where $\mathcal{D}$ is a given collection of definable sets. In a complete theory a definable set is determined by the value it has at a single model, this is of course false for $\infty$-definable sets.

We write: a $a \in D$ to mean: $a \in D(M)$ for some $M \models T$. It is customary, since Shelah, to choose a single universal domain $U$ embedding all “small” models, and let $a \in D$ mean: $a \in D(U)$; we will not require this interpretation, but the reader is welcome to take it.

We will sometimes consider imaginary sorts. If $D$ is a definable set, and $E$ a definable equivalence relation on $D$, then $D/E$ may be considered to be an imaginary sort; as a definable set it is just the functor $M \mapsto D(M)/E(M)$. A definable subset of a product $\Pi_{i=1}^n D_i / E_i$ of imaginary sorts (and ordinary sorts) is taken to be a subset whose preimage in $\Pi_{i=1}^n D_i$ is definable; the notion of a definable function is thus also defined. In this way the imaginary sorts can be treated on the same footing as the others. The set of all elements of all imaginary sorts of a structure $M$ is denoted $M^{eq}$. It is easy to construct a theory $T^{eq}$ in a language $L^{eq}$ whose category of models is (essentially) $\{ M^{eq} : M \models T \}$. See [34], [30], §16d.

Given a definable set $D \subseteq S \times X$, where $S, X$ are definable sets, and given $s \in S$, let $D(s) = \{ x \in X : (s, x) \in D \}$. Thus $D$ is viewed as a family of definable subsets of $X$, namely $\{ D(s) : s \in S \}$. If $s \neq s'$ implies $D(s) \neq D(s')$, we say that the parameters are canonical, or that $s$ is a code for $D(s)$. In particular, if $E$ is a definable equivalence relation, the imaginary elements $a / E$ can be considered as codes for the classes of $E$.

$T$ is said to eliminate imaginaries if every imaginary sort admits a definable injection into a product of some of the sorts of $L$. For instance, the theory of algebraically closed fields eliminates imaginaries. See [31] for an excellent exposition of these issues. We note that $T$ admits elimination of imaginaries iff for any family $D \subseteq S \times X$ there exists a family $D' \subseteq S' \times X$ such that for any $t \in S$ there exists a unique $t' \in S'$ with $D(t) = D'(t')$.

(Recall that $t \in S$ means: $t \in S(M)$ for some $M \models T$. The uniqueness of $t'$ implies in this case that one can choose $t' \in S'(M)$ too.) In this case we also say that $t'$ is called a canonical parameter or code for $D(t)$.

**Example 2.1.** let $b$ be a nondegenerate closed ball in a model the theory ACVF of algebraically closed valued fields. Then $b = \{ x : val(x-c) \geq val(c-c') \}$ for some elements $c \neq c'$ of the field. $b$ is coded by $\tilde{b} = (c, c')/E$, where $(c, c')E(d,d')$ iff $val(c-c') = val(d-d') \leq val(c-d)$. However we often fail to distinguish notationally between $b$ and $\tilde{b}$, and in particular we write $A(b) = A(\tilde{b})$.

The only imaginary sorts that will really be essential for us are the sorts $\mathcal{B}$ of closed and open balls. The closed balls around 0 can be identified with their radius, hence the valuation group $\Gamma(M) = VF^*(M)/\mathcal{O}^*(M)$ of a valued field $M$ is embedded as part of $\mathcal{B}$. 
Notation Let $\mathfrak{B} = \mathfrak{B}^o \cup \mathfrak{B}^c$, the sorts of open and closed sub-balls of VF. Let $\Gamma^+ = \{\gamma \in \Gamma : \gamma \geq 0\}$.

$$\mathfrak{B}^c = \bigcup_{\gamma \in \Gamma} \mathfrak{B}_\gamma^c, \quad \mathfrak{B}_\gamma^c = \text{VF}/\gamma^0$$

$$\mathfrak{B}^o = \bigcup_{\gamma \in \Gamma} \mathfrak{B}_\gamma^o, \quad \mathfrak{B}_\gamma^o = \text{VF}/\gamma^M$$

Here $\gamma^M = \{x \in \text{VF} : \text{val}(x) > \gamma\}$, $\gamma^0 = \{x \in \text{RES} : \text{val}(x) \geq \gamma\}$. The elements of $\mathfrak{B}^c_\gamma$, $fB_n^c$ will be referred to as \textit{closed and open balls of valuative radius $\gamma$}; though this valuative definition of radius means that bigger balls have smaller radius. The word “distance” will be used similarly.

By a \textit{thin annulus} we will mean: a closed ball of valuative radius $\gamma$, with an open ball of valuative radius $\gamma$ removed.

Fix a model $M$ of $T$. A \textit{substructure} $A$ of $M$ (written: $A \leq M$) consists of a subset $A_S$ of $S(M)$, for each sort $S$ of $L$, closed under all definable functions of $T$. For example, the substructures of models of $T_{\text{fields}}$ are the integral domains.

In general, the \textit{definable closure} of a set $A_0 \subset M$ is the smallest substructure containing $A_0$; it is denoted $\text{cl}(A_0)$ or $<A_0>$. An element of $<A_0>$ can be written as $g(a_1, \ldots, a_n)$ with $a_i \in A_0$ and $g$ a definable function; i.e., it is an element satisfying a formula $\phi(x, a_1, \ldots, a_n)$ of $L_{A_0}$ in one variable that has exactly one solution in $M$. If $A$ is a substructure, $\text{cl}(A \cup \{c\})$ is also denoted $A(c)$. These notions apply equally when $A, c$ contain elements of the imaginary sorts. If $B$ is contained in sorts $S_1, \ldots, S_m$, then $\text{cl}(B)$ is said to be an $S_1, \ldots, S_m$-generated substructure. In the special case of valued fields, where one of the sorts VF is the “main” valued field sort, a VF-generated structure will be said to be field-generated, or sometimes just “a field”.

For any definable set $D$, let $D(A)$ be the set of points of $D(M)$ with coordinates in $A$. If $S = D/E$ is an imaginary sort, $S(A)$ is the set of $a \in S$ whose preimage is defined over $A$. We have $D(A)/E(A) \subseteq S(A)$. $D(A)/E(A)$ is of course closed under definable functions $S^n \to S$ that lift to definable functions $D^n \to D$, but it is not necessarily closed under arbitrary definable functions, i.e functions whose graph is the image of a definable subset of $D^n \times D$. For example $x \mapsto (1/n)x$ is a definable function on the value group of a model of ACVF, but if $A \leq M \models \text{ACVF}$, $\Gamma(A)$ need not be divisible.

When $A \leq M, B \leq N$ with $M, N \models T$, a function $f : A \to B$ is called a (partial) elementary embedding $(A, M) \to (B, N)$ if for any definable set $D$ of $L$, $f^{-1}D(B) = D(A)$. In particular, when $A = M, B = N$, one say that $M$ is an elementary submodel of $N$.

By a \textit{constructible set} over $A$, we mean the functor $L \mapsto \phi(L)$ on models $M \models T_A$, where $\phi = \phi(x_1, \ldots, x_n, a_1, \ldots, a_m)$ is a quantifier-free formula with parameters from $A$.

We say that $T$ \textit{admits quantifier-elimination} if every definable set coincides with a constructible set. It follows in this case that for any $A$, any $A$-definable set is $A$-constructible. When $T$ admits quantifier elimination, $f : A \to B$ is a partial elementary embedding iff it is an embedding of structures.

The theories (1-5) of §2.1 admit quantifier elimination in their natural algebraic languages (theorems of Tarski-Chevalley and Robinson; cf. [16].) The sixth admits quantifier elimination in a language that needs to be formulated with more care, see [23].

In all of this paper except for §12.1, §12.3, we will use only structural properties of definable sets, and not explicit formulas. In this situation quantifier elimination can be assumed softly, by merely increasing the language by definition so that all definable sets become equivalent to quantifier-free ones. The above distinctions will only directly come into play in the two sections §12.1, §12.3.
If \( A \leq M \models T \), \( L_A \) is the language \( L \) expanded by a constant \( c_A \) for each element \( a \) of \( A \), so that an \( L_A \)-structure is the same as an \( L \)-structure \( M \) together with a function \( \varphi \colon A_S \to \varphi(S(M)) \), for each sort \( S \). \( T_A \) is the set of \( L_A \) sentences true in \( M \) when the constant symbol \( c_A \) is interpreted as \( a \); the models of \( T_A \) are models \( M \) of \( T \), together with an isomorphic embedding of \( A \) as a substructure of \( M \). In particular, \( M \) with the inclusion of \( A \) in \( M \) is an \( L_A \)-structure denoted \( M_A \). For any subset \( A_0 \subseteq M \), we write \( T_{A_0} \) for \( T < A_0 > \), where \( < A_0 > \) is the substructure generated by \( A_0 \).

A definable set of \( T_A \) will also be referred to as \( A \)-definable; similarly for other notions such as those defined just below.

A parametrically definable set of \( T \) is by definition a \( T_A \)-definable set for some \( A \).

An almost definable set is the union of classes of a definable equivalence relation with finitely many classes. An element \( e \) is called algebraic (resp. definable) if the singleton set \( \{e\} \) is almost definable (resp. definable). When \( T \) is a complete theory, the set of algebraic (definable) elements of a model \( M \) of \( T \) forms a substructure that does not depend on \( M \), up to (a unique) isomorphism.

Let \( A_0 \subseteq M \models T \); the set of \( e \in M \) almost definable over \( A_0 \) is called the algebraic closure of \( A_0 \), \( \text{acl}(A_0) \). If \( A_0 \) is contained in sorts \( S_1, \ldots, S_n \), any substructure of \( \text{acl}(A_0) \) containing \( \text{acl}(A_0) \) is said to be almost \( S_1, \ldots, S_n \)-generated.

**Example 2.2.** If a definable set \( D \) carries a definable linear ordering, then every algebraic element of \( D \) is definable. This is because the least element of a finite definable set \( F \) is clearly definable; the rest are contained in a smaller finite definable subset of \( D \), so are definable by induction.

If in addition \( D \) has elimination of imaginaries, and \( Y \) is almost definable and definable with parameters from \( D \), then \( Y \) is definable. Indeed using elimination of imaginaries in \( D \), the set \( Y \) can be defined using canonical parameters. These are algebraic elements of \( D \), hence definable.

Two definable functions \( f : X \rightarrow Y, f' : X \rightarrow Y' \) will be called isogenous if for all \( x \in X \), \( \text{acl}(f(x)) = \text{acl}(f'(x)) \).

2.1.1. **Compactness.** Compactness often allows to replace arguments in relative dimension one over a definable set, by arguments in dimension one over a different base structure. Here is an example:

**Lemma 2.3.** Let \( f_i : X_i \rightarrow Y \) be definable maps between definable sets of \( T \) \( (i = 1, 2, \ldots) \). Assume that for any \( M \models T \) and \( b \in Y(M) \), \( X_1(b) := f_1^{-1}(b) \) is \( T_b \)-definably isomorphic to \( X_2(b) = f_2^{-1}(b) \). Then \( X_1, X_2 \) are definably isomorphic.

**Proof.** Let \( \mathcal{F} \) be the family of pairs \( (U, h) \), where \( U \) is a definable subset of \( Y \), and \( h : f_1^{-1}U \rightarrow f_2^{-1}U \) is a definable bijection.

**Claim** For any \( b \in Y(M) \), \( M \models T \), there exists \((U, h) \in \mathcal{F} \) with \( b \in U \).

**Proof.** Let \( b \in Y(M) \). There exists a \( T_b \)-definable bijection \( X_1(b) \rightarrow X_2(b) \). This bijection can be written: \( x \mapsto g(x, b) \), where \( g \) is a definable function. Let \( U = \{ y \in Y : (x \mapsto g(x, y)) \text{ is a bijection } X_1(y) \rightarrow X_2(y) \} \). Then \( (U, g(x, f_1(x))) \in \mathcal{F} \), and \( b \in U \). \( \square \)

Now by compactness, there exist a finite number of definable subsets \( U_1, \ldots, U_k \) of \( Y \), with \( Y = \bigcup_i U_i \), and with \((U_i, h_i) \in \mathcal{F} \) for some \( h_i \). Let \( U_i' = U_i \setminus (U_1 \cup \ldots \cup U_{i-1}) \), and define \( h = \bigcup_i h_i |_{U_i'} \). Then \( h : X_1 \rightarrow X_2 \) is the required bijection. \( \square \)

Here is another example of the use of compactness:

**Example 2.4.** If \( D \) is a definable set, and for any \( a,b \in D \), \( a \in \text{acl}(b) \), then \( D \) is finite. More generally, if \( a \in \text{acl}(b) \) for any \( b \in D \), then \( a \in \text{acl}(\emptyset) \).
Proof. We prove the first statement, the second being similar. For any model $M$, pick $a \in M$; then $D(M) \subseteq \acl(a)$. For $b \in \acl(a)$, let $\phi_b$ be the formula $x \neq b \& D(x)$. So the set of formulas $Th(M) \cup \{\phi_b\}$ has no common solution. By compactness, some finite subset already has no solution; this is only possible if $D(M)$ is finite. \qed

2.1.2. Transitivity, orthogonality. A definable set $D$ is transitive if it has no proper, nonempty definable subsets. (The usual word is “atomic”. One also says that $D$ generates a complete type.) It is (finitely) primitive if it admits no nontrivial definable equivalence relation (with finitely many classes).

Remark 2.5. Let $A$ be a VF-generated substructure of a model of ACVF. When $A$ is VF-generated, we will see that an $\ACVF_A$-definable ball $b$ is never transitive in $\ACVF_A$; indeed it always contains an $A$-definable finite set. But $b$ is always $\ACVF_{A(b)}$-definable, and quite often it is transitive; cf. Lemma 3.8.

Two definable sets $D, D'$ are said to be orthogonal if any definable subset of $D^n \times D'$ is a finite union of rectangles $E \times F$, $E \subseteq D^n$, $F \subseteq D'$. In this case, the rectangles $E, F$ can be taken to be almost definable. If the rectangles can actually be taken definable, we say $D, D'$ are strongly orthogonal.

2.1.3. Types. Let $S$ be a product of sorts, and let $M \models T, a \in S(M)$. We write $tp(a) = tp(a; M)$ (the type of $a$) for the set of definable sets $D$ with $a \in D$; when $p = tp(a)$ we write $a \models p$. A complete type is the type of some element in some model. If $q = tp(a)$, we say $a$ is a realization of $q$. The set $\mathcal{T}_S$ of complete types belonging to $S$ can be topologized: a basic open set is the set of types including a given definable set $D$. The compactness theorem of model theory implies that this is a compact topological space: if $\{D_i\}$ is any collection of definable sets with nonempty finite intersections, the compactness theorem asserts the existence of $M \models T$ with $\cap_i D_i(M) \neq \emptyset$.

The compactness theorem is often used by way of a construction called saturated models; cf. [9]. These are models where all types over “small” sets are realized. They enjoy excellent Galois-theoretic properties: in particular if $M$ is saturated, then $\acl(A_0) = \Fix Aut(M/A_0)$ for any finite $A_0 \subseteq M$. If $D$ is $\acl(A_0)$-definable, then there exists an $A_0$-definable $D'$ which is a finite union of $Aut(M/A_0)$-conjugates of $D$.

A type $p$ can also be identified with the functor $P$ from models of $T$ (under elementary embeddings) into sets; $P(M) = \{a \in M : a \models p\}$. As with definable sets, we speak as if $P$ is simply a set. Unlike definable sets, the value of $P(M)$ at a single model does not determine $P$ (it could be empty; but it does determine $P$ if $M$ is sufficiently saturated.)

Any definable map $f : S \to S'$ induces a map $f_\ast : \mathcal{T}_S \to \mathcal{T}_{S'}$; as another consequence of the compactness theorem, $f_\ast$ is continuous. We also have a restriction map from types of $T_A$ to types of $T$, $tp_{T(A)}(a) \mapsto tp_T(a)$.

If $L \subseteq L'$ and $T \subseteq T'$, we say that $T'$ is an expansion of $T$. In this case any $T'$-type $p'$ restricts to a $T$-type $p$. If $p'$ is the unique type of $T'$ extending $p$, we say that $p$ implies $p'$.

The simplest kind of expansion is an expansion by constants, i.e. a theory $T_A$ (where $A \subseteq M \models T$.) If $c \in M^n$, or more generally if $c \in M^{eq}$, the type of $c$ for $M_A$ is denoted $tp(c/A)$. It is rare for $tp(c)$ to imply $tp(c/A)$, but significant when it happens.

An instance of this is strong orthogonality: it is easy to see that strong orthogonality of two definable sets $D, D'$ is equivalent to the following condition:

(*) If $A'$ is generated by elements of $D'$, then any type of elements of $D$ generates a complete type over $A'$.

The asymmetry in (*) is therefore only apparent.

Similarly, we have:
Lemma 2.6. Let $D, D'$ be definable sets. Then (1) $\iff$ (2), (3) $\iff$ (4).

1. Every definable function $f : D \to D'$ is piecewise constant, i.e. there exists a partition $D = \bigcup_{i=1}^{n} D_i$ of $D$ into definable sets, with $f$ constant on $D_i$.

2. If $d \in D$, $d' \in D'$, then $d' \in acl(d)$.

3. If $f : E \to D$ is a definable finite-to-one map, and $g : E \to D'$ is definable, then $g(E)$ is finite.

4. If $d \in D$, $d' \in D'$, then $d' \in acl(d)$.

Proof. Let us show that (3) implies (4). Let $M \models T$, $d \in D(M)$, $d' \in D'(M)$, $d' \in acl(d)$. Then $d'$ lies in some finite $T_d$-definable set $D'(d) \subseteq D'$. Since $T_d$ is obtained from $T$ by adding a constant symbol for $d$, there exists a formula $\phi(x, y)$ of the language of $T$ and some $m$ such that $M \models \phi(d, d')$ and $M \models (\exists z^{m})(\phi(d, z))$. Let $X_0 = \{(x : (\exists z^{m})(\phi(x, y)), E = \{(x, y) : x \in X_0, \phi(x, y))\}$, $f(x, y) = x$, $g(x, y) = y$. Then by (3) $g(E)$ is finite, but $d' \in g(E)$, so $d' \in acl(\emptyset)$.

Next, (4) implies (3): let $f, E, g$ be as in (3), and suppose $g(E)$ is infinite. In particular, for any finite $F \subseteq acl(\emptyset)$ there exists $d' \in g(E) \setminus F$. Thus the family consisting of $g(E)$ and the complement of all finite definable sets has nonempty intersections of finite subfamilies, so by the compactness theorem, in some $M \models T$ there exists $d' \in g(E) \setminus acl(\emptyset)$.

Let $d \in E(M)$ be such that $d' = g(d)$. Then $d' \in acl(f(d))$, but $f(d) \in D$, contradicting (4).

The equivalence of (1), (2) is similar. $\square$

Example 2.7. Let $P$ be a complete type, and $f$ a definable function. Then $f(P)$ is a complete type $P'$. If $f$ is injective on $P$ then there exist definable $D \supseteq P$, $D' \supseteq P'$ such that $f$ restricts to a bijection of $D$ with $D'$.

Proof. For any definable $D'$, $f^{-1}D'$ is definable, so $P \subseteq f^{-1}D'$ or $P \cap f^{-1}D' = \emptyset$. Thus $P' \subseteq D'$ or $P' \cap D' = \emptyset$. So $P'$ is complete.

Let $\{D_i\}$ be the family of definable sets containing $P$. Let $R_i = \{(x, y) \in D_i^2 : x \neq y, f(x) = f(y)\}$. Then $\bigcap_i R_i = \emptyset$. Since the family of $\{D_i\}$ is closed under finite intersections, it follows from the compactness theorem that for some $i$, $R_i = \emptyset$. Let $D = D_i$, $D' = f(D)$. $\square$

2.1.4. Naming almost definable sets. As special case of an expansion by constants, we can move from a complete theory $T$ to the theory $T_A$, where $A = acl(\emptyset)$ is the set of all algebraic elements of a model $M$ of $T$, including imaginaries. The effect is a theory where each class of any definable equivalence relation $E$ with finitely many classes is definable. Since $T$ is complete, the isomorphism type of $acl(\emptyset)$ in a model $M$ does not depend on the choice of model; so the theory $T_A$ is determined. A definable set in this theory corresponds to an almost definable set in $T$.

When $D$ is a constructible set, $T|D$ denotes the theory induced on $D$: if $T$ eliminates quantifiers, the language is just the restriction to $D$ of the relations and functions of $L$. If the language is countable, the countable models of $D_A$ are of the form $D(M)$, where $M$ is a countable model of $T_A$.

2.1.5. Stable embeddedness. A definable subset $D$ of any product of sorts (possibly imaginary) is called stably embedded (in $T$) if for any $A$, any $T_A$-definable subset of $D^m$ is $T_B$-definable for some $B \subseteq D$. For example, the set of open balls is not stably embedded in ACVF, since the set of open balls containing a point $a \in K$ cannot in general be defined using a finite number of balls.

Lemma 2.8. Let $D$ be a family of sorts of $L$; let $T|D$ be the theory induced on the sorts $D$; If $D$ is stably embedded and $T|D$ admits elimination of imaginaries, then for any definable $P$ and
definable $S \subseteq P \times D^n$, viewed as a $P$-indexed family of subsets $S(a) \subseteq D^n, a \in P$, we have a definable function $f : P \to D^n$, with $f(a)$ a canonical parameter for $S(a)$.

Proof. By stable embeddedness there exists a family $S' \subseteq P' \times D^n$ yielding the same family, i.e. $S(a) : a \in P = \{S'(a') : a' \in P'\}$, and with $P' \subseteq D^n$; using elimination of imaginaries we can take $S'$ to be a canonical family; now $a$ define $f(a)$ to be the unique $a' \in P'$ with $S(a) = S'(a')$.

\begin{corollary}
If $D$ is stably embedded and admits elimination of imaginaries, then for any substructure $A$,
\begin{enumerate}
\item $(T_A)|D = (T)|D_{A \cap D}$
\item for $a \in A$, $tp(a|A \cap D)$ implies $tp(a/D)$.
\end{enumerate}
\end{corollary}

Examples of definable sets of ACVF satisfying the hypotheses include the residue field $k$, or the value group $\Gamma$, as well as $RV \cup \Gamma$. The stable embeddedness in this case is an immediate consequence of quantifier elimination; cf. Lemma 3.30.

If $M$ is saturated and $D$ is stably embedded in $T$, then we have an exact sequence
$$1 \to Aut(M/D(M)) \to Aut(M) \to Aut(D(M)) \to 1$$
where $Aut(M/D(M))$ is the group of automorphisms of $M$ fixing $D(M)$ pointwise, and $Aut(D(M))$ is the group of permutations of $D(M)$ preserving all definable relations. Moreover $Aut(M/D(M))$ has a good Galois theory; in particular elements with a finite orbit are almost definable over some finite subset of $D$. This and some other characterizations can be found in the appendix to [5].

2.1.6. Generic types. Let $T$ be a complete theory with quantifier-elimination. Let $\mathcal{C}$ be the category of substructures of models of $T$, with $L$-embeddings, and let $\mathcal{S}$ be the category of pairs $(A,p)$ with $A \in \text{Ob} \mathcal{C}$ and $p$ a type over $A$. We define $\text{Mor} \big((A,p),(B,q)\big) = \{f \in \text{Mor} \mathcal{C}(A,B) : f^*(q) = p\}$.

By a generic type we will mean a function $p$ on $\text{Ob} \mathcal{C}$, denoted $A \mapsto (p|A)$, such that $A \mapsto (A,p|A)$ is a functor $\mathcal{C} \to \mathcal{S}$. One example, when $T$ is the theory of algebraically closed fields, is provided by any absolutely irreducible variety $V$: given a field $F$, let $p|F$ be the type of an $F$-generic point of $V$, i.e. the type of a point of $V(L)$ avoiding $U(L)$ for every proper $F$-subvariety $U$ of $V$, where $L$ is some extension field of $F$. Other examples will be given below, beginning with Example 3.3.

\begin{lemma}
Let $p$ be a generic type of $T$, and let $M \models T, a, b \in M$. Let $c \models p|M$.
\begin{enumerate}
\item If $a \notin \text{dcl}(\emptyset)$, then $a \notin \text{dcl}(c)$.
\item If $a \notin \text{acl}(\emptyset)$, then $a \notin \text{acl}(c)$.
\item If $a \notin \text{acl}(b)$, then $a \notin \text{acl}(b,c)$.
\end{enumerate}
\end{lemma}

Proof. (1) Since $a \notin \text{dcl}(\emptyset)$, there exists $a' \neq a$ with $tp(a) = tp(a')$. Let $c' \models p| < \{a,a'\} >$. Since $tp(a) = tp(a')$, there exists an isomorphism $< a > \leftrightarrow < a' >$; by functoriality of $p$, $tp(a,c) = tp(a',c')$. If $a \in \text{dcl}(c)$, then $a$ is the unique realization of $tp(a/c)$, so $a = a'$; a contradiction.

(2) If $a \in \text{acl}(c)$, then for some $n$ there are at most $n$ realizations of $tp(a/c)$. Since $a \notin \text{acl}(\emptyset)$, there exist distinct realizations $a_0, \ldots, a_n$ of $tp(a)$. Proceed as in (1) to get a contradiction.

(3) By (2) for $T_{<\emptyset>}$. 
\hfill $\square$
2.2. Grothendieck rings. 

We define the Grothendieck group and associated objects of a theory $T$; cf. [10]. $\text{Def}(T)$ is the category of definable sets and functions. Let $\mathcal{C}$ be a subcategory of $\text{Def}(T)$. We assume $\text{Mor}(X,Y)$ is a sheaf on $X$: if $X_1 = X_2 \cup X_3$ are subobjects of $X$, and $f_i \in \text{Mor}(X_i,Y)$ with $f_1|(X_2 \cap X_3) = f_2|(X_2 \cap X_3)$, then there exists $f \in \text{Mor}(X,Y)$ with $f|X_i = f_i$. Thus the disjoint union of two constructible sets in $\text{Ob}\mathcal{C}$ is also the category theoretic disjoint sum.

If only the objects are given, we will assume $\text{Mor}\mathcal{C}$ is the collection of all definable bijections between them.

The Grothendieck semigroup $K_+(\mathcal{C})$ is defined to be the semigroup generated by the isomorphism classes $[X]$ of elements $X \in \text{Ob}\mathcal{C}$, subject to the relation:

$$[X] + [Y] = [X \cup Y] + [X \cap Y]$$

In most cases, $\mathcal{C}$ has disjoint unions; then the elements of $K_+(\mathcal{C})$ are precisely the isomorphism classes of $\mathcal{C}$.

If $\mathcal{C}$ has Cartesian products, we have a semiring structure given by:

$$[X][Y] = [X \times Y]$$

In all cases we will consider when products are present, the symmetry isomorphism $X \times Y \rightarrow Y \times X$ will be in the category, as well as the associativity morphisms, so that $K_+(\mathcal{C})$ is a commutative semiring.

(The assumption on Cartesian products is taken to include the presence of an object $\{p\} = X^0$ such that the bijections $X \rightarrow \{p\} \times X$, $x \mapsto (p,x)$, and $X \rightarrow X \times \{p\}$, $x \mapsto (x,p)$, are in $\text{Mor}_\mathcal{C}$ for all $X \in \text{Ob}\mathcal{C}$. All such $p$ gives the same element $1 = [\{p\}] \in K(\mathcal{C})$, which serves as the identity element of the semiring.)

Let $K(\mathcal{C})$ be the Grothendieck group, the formal groupification of $K_+(\mathcal{C})$. When $\mathcal{C}$ has products, $K(\mathcal{C})$ is a commutative ring.

We will often have dimension filtrations on out categories, and hence on the semi-ring.

By an semi-ring ideal we mean a congruence relation, i.e. an equivalence relation on the semi-ring $R$ that is a sub-semi-ring of $R \times R$. To show that an equivalence relation $E$ is a congruence on a commutative semi-ring $R$, it suffices to check that if $(a,b) \in E$ then $(a+c,b+c) \in E$ and $(ac,bc) \in E$.

Remark When $T$ is incomplete, let $S$ be the (compact, totally disconnected) space of completions of $T$. Then $\{K(t) : t \in S\}$ are the fibers of a sheaf of rings over $S$. $K(T)$ can be identified with the ring of continuous sections of this sheaf. In this sense, Grothendieck rings reduce to the case of complete theories.

This last remark is significant even when $T$ is complete: if one adds a constant symbol $c$ to the language, $T$ becomes incomplete, and so the Grothendieck ring of $T$ in $L(c)$ is the Boolean power of $K(T_0)$, where $T_0$ ranges over all $L(c)$-completions of $T$. Say $c$ is a constant for an element of a sort $S$. Then an $L(c)$-definable subset of a sort $S'$ corresponds to an $L$-definable subset of $S \times S'$. This allows an inductive analysis of the Grothendieck ring of a structure, given good information about definable sets in one variable (cf. Lemma 2.3).

2.2.1. Groups of functions into $\mathcal{R}$. Let $\mathcal{C}(T)$ be a subcategory of the category of definable sets and bijections, defined systematically for $T$ and for expansions by constants $T$. Let $\mathcal{R}(T) = K_+(\mathcal{C}(T))$ be the Grothendieck semigroup of $\mathcal{C}(T)$. When $V$ is a definable set, we let $\mathcal{C}_V$, $\mathcal{R}_V$ denote the corresponding objects over $V$; the objects of $\mathcal{C}_V$ are definable sets $X \subseteq (V \times W)$ such that for any $a \in V$, $X_a \in \mathcal{C}_a$, and similarly the morphisms. In practice,
\( \mathcal{R} \) will be the Grothendieck semigroup of all definable sets and definable isomorphisms satisfying some definable conditions, such as a boundedness condition on the objects, or a "measure preservation" condition on the definable bijections.

To formalize the notion of "definable function into \( \mathcal{R} \)" we will need to look at classes \( X_a \) of parametrically definable sets. The class of \( X_a \) makes sense only in the Grothendieck groups associated with \( T_a \), not \( T \). Moreover equality of such classes, say of \( X_a \) and of \( X_b \), begins to make sense only in Grothendieck groups of \( T_{(a,b)} \). Expressions like

\[
[X] = [Y]
\]

will therefore mean: \( X,Y \) are both definable in \( T_{a,b} \) \([X],[Y]\) denote their classes in the Grothendieck group of \( T_{a,b} \), and these classes are equal.

If \( V \) is a definable set, we define the semigroup of definable functions \( V \to \mathcal{R} \), denoted \( Fn(V,\mathcal{R}) \). An element of \( Fn(V,\mathcal{R}) \) is represented by a definable \( X \in \mathcal{E}_V \), viewed as the function:

\[
a \mapsto [X_a], \text{ where } [X_a] \text{ is a class in } \mathcal{R}_a. \quad X, X' \text{ represent the same function if for all } a, [X_a], [X'_a] \text{ are the same element of } \mathcal{R}_a. \quad \text{Note that despite the name, the elements of } Fn(V,\mathcal{R}) \text{ should actually be viewed as sections } V \to \prod_{a \in V} \mathcal{E}_a.
\]

Addition is given by disjoint union in the image (i.e. disjoint union over \( X \)).

Usually \( \mathcal{R} \) has a natural grading by dimension; in this case \( Fn(V,\mathcal{R}) \) inherits the grading.

Assume \( V \) is a definable group and \( \mathcal{R} = K_+(T) \) is the Grothendieck semiring of all definable sets and functions of \( T \), there is a natural convolution product on \( Fn(V,\mathcal{R}) \). If \( h_i(a) = [H_i(a)] \), \( H_i \subset V \times B_i \), the convolution \( h_1 \ast h_2 \) is represented by

\[
H = \{(a_1 + a_2, (a_1, a_2, y_1, y_2)) : (a_i, y_i) \in H_i \} \subseteq V \times (V^2 \times B_1 \times B_2)
\]

so that \( h_1 \ast h_2(a) = H(a) = \{(a_1, a_2, y_1, y_2) : (a_i, y_i) \in H_i, a_1 + a_2 = a \} \).

2.2.2. Grothendieck groups of orthogonal sets.

**Lemma 2.11.** Let \( T \) be a theory with two strongly orthogonal definable sets \( D_1, D_2, D_{12} = D_1 \times D_2 \). Let \( K_+D_{12}[n] \) be the Grothendieck semigroup of definable subsets of \( D_{12}^n \). Then \( \mathcal{K}_+D_{12}[n] \simeq [K_+D_{12}[1][n][K_+D_{12}[2][n]]

**Proof.** This reduces to \( n = 1 \). Given definable sets \( X_i \subseteq D_{12}^n \), it is clear that the class of \( X_1 \times X_2 \) in \( K_+D_{12}[n] \) depends only on the classes of \( X_i \) on \( D_{12}[n] \). Define \( [X_1][X_2] = [X_1 \times X_2] \). This is clearly \( \mathcal{E} \)-bilinear, and so extends to a homomorphism \( \eta : K_+D_{12}[1] \times K_+D_{12}[2] \to K_+D_{12}[1] \).

By strong orthogonality, \( \eta \) is surjective.

To prove injectivity, note that any element of \( K_+D_{12}[n][K_+D_{12}[n] \) can be written \( \sum [X_i] \otimes [X'_i] \), with \( X_i \) pairwise disjoint. To see this, begin with some expression \( \sum [X_i] \otimes [X'_j] \); use the relation \( [X'] \otimes [Y'] \otimes [Y'] = [X'] \otimes [Y'] \) to replace the \( X_i \) by the atoms of the Boolean algebra they generate, so that the new \( X_i \) are equal or disjoint; finally use the relation \( [X' \otimes Y'] = [X'] \otimes Y' \) to amalgamate the terms with equal first coordinate.

Hence it suffices to show that if \( \bigcup X_i \times Y_j = \bigcup Y_i \times Y'_j \), with the \( X_i \) and the \( Y_i \) pairwise disjoint, then \( \sum [X_i] \times [Y_j] = \sum [Y_i] \times [Y'_j] \). Let \( F : \bigcup X_i \times Y_j \to \bigcup Y_i \times Y'_j \) be a definable bijection. By strong orthogonality, the graph of \( F \) is a disjoint union of rectangles. Since \( F \) is a bijection, it is easy to see that each of these rectangles has the form \( f_i \times f_j \), where for \( \nu = 1,2 \), \( f_{\nu} : X_{\nu}(k) \to Y_{\nu}(k) \) is a bijection from a subset of \( \bigcup X_{\nu} \) to a subset of \( \bigcup Y_{\nu} \). The rest follows by an easy combinatorial argument; we omit the details, since a somewhat more complicated case will be needed and proved later, see Proposition 10.2. \( \square \)
2.2.3. Integration by parts. The following will be used only in §9, to study the Grothendieck semiring of the valuation group.

**Definition 2.12.** Let us say that $Y \in \text{Ob } \mathcal{C}$ is treated as discrete if for any $X \in \text{Ob } \mathcal{C}$ and any definable $F \subset X \times Y$ such that $T \models F$ is the graph of a function, the projection map $F \to X$ is an invertible element of $\text{Mor}_\mathcal{C}(F,X)$.

To explain the terminology, suppose each $X \in \text{Ob } \mathcal{C}$ is endowed with a measure $\mu_X$, and $\mathcal{C}$ is the category of measure preserving maps. If $\mu_Y$ is the counting measure, and $\mu_{X \times Y}$ is the product measure, then for any function $f : X \to Y$, $x \mapsto (x, f(x))$ is measure preserving.

We will assume $\mathcal{C}$ is closed under products.

If $Y_1, Y_2$ are treated by $\mathcal{C}$ as discrete, so is $Y_1 \times Y_2$; if $F \subset X \times (Y_1 \times Y_2)$ is the graph of a function $X \to (Y_1 \times Y_2)$, then the projection to $F_1 \subset X \times Y_1$ is the graph of a function, hence the projection $F_1 \to X$ is in $\mathcal{C}$; now $F \subset (F_1 \times Y_2)$ is the graph of a function, and so $F \to F_1$ is invertibly represented too; thus so is the composition.) In particular if $Y$ is discretely treated, any bijection $U \to U'$ between subsets of $Y^n$ is represented in $\mathcal{C}$.

If $\mathcal{R}$ is a Grothendieck group or semigroup, we write $[X] = [Y]$ to mean that $X, Y$ have the same class in $\mathcal{R}$.

**Lemma 2.13.** Let $f, f' \subset X \times L$ be objects of $\mathcal{C}$ such that $[f(c)] = [f'(c)]$ for any $c$ in $X$. Then $[f] = [f']$. Similarly for $K_+$. 

*Proof.* By assumption, there exists $g(c)$ such that $f(c) + g(c), f'(c) + g(c)$ are $\mathcal{C}$-isomorphic. By compactness (cf. end of proof of Lemma 2.3) this must be uniform (piecewise in $L$, and hence by gluing globally): there exists a definable $g \subset Z \times L$ and a definable isomorphism $f + g \simeq f' + g$, inducing the isomorphisms of each fiber. By definition of $\mathcal{C}$, and since $\mathcal{C}$ is closed under finite gluing, $f + g, f' + g$ are in $\text{Ob } \mathcal{C}$ and the isomorphism between them is in $\text{Mor } \mathcal{C}$. 

Let $L$ be an object of $\mathcal{C}$, treated as discrete in $\mathcal{C}$, and assume given a definable partial ordering on $L$.

**Notation 2.14.** Let $f \subset X \times L$. For $y \in L$, let $f(y) = \{x : (x, y) \in f\}$. Denote: $\sum_{\gamma < \beta} f(\gamma) = \{ (x,y) : x \in f(y), y < \gamma \}$

**Notation 2.15.** Let $\phi : L \to K(X)$ be a constructible function, represented by $f \subset X \times L$; so that $\phi(y) = \{ f(y) \}$, $f(y) = \{ x : (x, y) \in f \}$. Denote: $\sum_{\gamma < \beta} \phi(\gamma) = \{ (x,y) : x \in f(y), y < \gamma \}$

Note by Lemma 2.13 that this is well-defined.

Below, we write $fg$ for the pointwise product of two functions in $K(\mathcal{C})$; $[fg(y)] = [f(y) \times g(y)]$.

**Lemma 2.16** (Integration by parts). Let $\Gamma$ be an object of $\mathcal{C}$, treated as discrete in $\mathcal{C}$, and assume given a definable ordering of $\Gamma$. Let $f \subset X \times \Gamma$, $F(\beta) = \sum_{\gamma < \beta} f(\gamma), g \subset Y \times \Gamma$, $G(\beta) = \sum_{\gamma \leq \beta} g(\gamma)$.

Then

$$F G(\beta) = \sum_{\gamma < \beta} f G(\gamma) + \sum_{\gamma \leq \beta} F g(\gamma)$$

*Proof.* Clearly

$$FG(\beta) = \sum_{\gamma < \beta, \gamma' \leq \beta} f(\gamma)g(\gamma')$$

We split this into two sets: $\gamma < \gamma'$, and $\gamma' \leq \gamma$. Now

$$\sum_{\gamma < \gamma' \leq \beta} f(\gamma)g(\gamma') = \sum_{\gamma' \leq \beta} F(\gamma')g(\gamma')$$

$$\sum_{\gamma' \leq \gamma \leq \beta} f(\gamma)g(\gamma') = \sum_{\gamma < \beta} f(\gamma)G(\gamma')$$
The lemma follows. □

This is particularly useful when \( L \) is treated as discrete in \( \mathbb{C} \), since then, if the sets \( f(\gamma) \) are disjoint, \([f] = [\bigcup_{\gamma} f(\gamma)]\). Another version, with \( G(\beta) = \sum_{\gamma < \beta} g(\gamma) \):

\[
FG(\beta) = \sum_{\gamma < \beta} (fG + gF + fg)(\gamma)
\]

3. Some \( C \)-minimal geometry.

We will isolate the main properties of the theory \( ACVF \), and work with an arbitrary theory \( T \) satisfying these properties. This includes the rigid analytic expansions \( ACVF^R \) of [23].

The right general notion, \( C \)-minimality, has been introduced and studied in [15]. They obtain many of the results of the present section. Largely for expository reasons, we will describe a slightly less general version; it is essentially minimality with respect to an ultrametric structure in the sense of [30]. We will use notation suggestive of the case of valued fields; thus denoting the main sort by \( VF \), and a binary function by \( \text{val}(x - y) \). Some additional assumptions will be made explicit later on.

Let \( T \) be a theory in a language \( L \), extending a theory \( T \) in a language \( L \). \( T \) is said to be \( T \)-minimal if for any \( M \models T \), any \( L_M \)-formula in one variable is \( T_M \)-equivalent to an \( L_M \) formula.

More generally, if \( D \) is a definable subset of \( T \) (i.e. a formula of \( L \)), we say that \( D \) is \( T \)-minimal if for every for any \( M \models T \), any \( T_M \)-definable subset of \( D \) is \( T_M \)-equivalent to one defined by an \( L_M \) formula.

**Strong minimality.** Let \( L = \emptyset \). The only atomic formulas of \( L \) are thus equalities \( x \equiv y \) of two variables. \( T \) the theory of infinite sets. \( T \)-minimality is known as strong minimality; see [1], [28]. A theory \( T \) is strongly minimal iff for any \( M \models T \), any \( T_M \)-definable subset of \( M \) is finite or cofinite. For us the primary example of a strongly minimal theory is \( ACF \), the theory of algebraically closed fields.

Let \( M \models T \). If \( D \) is strongly minimal, and \( X \) a definable subset of \( D^* \), we define the \( D \)-dimension of \( X \) to be the least \( n \) such that \( X \) admits a \( T_M \)-definable map into \( D^n \) with finite fibers. In the situation we will work in, there will be more than one definable strongly minimal set up to isomorphism, and even up to definable isogeny; in particular there will be the various sets of \( RES_M \). However, between any of these, there exists an \( M \)-definable isogeny; so the \( k \)-dimension agrees with the \( D \)-dimension for any of them. We will call it the \( RES \)-dimension. It agrees with Morley rank, a notion defined in greater generality, that we will not otherwise need here.

**O-minimality.** \( L = \{<\} \), \( T = DLO \) the theory of dense linear orders without endpoints. (Cf. [9]) DLO minimality is known as \( O \)-minimality, and can also be stated thus: any \( T_M \)-definable subset of \( M \) is a finite union of points and intervals. This also forms the basis of an extensive theory; see [36].

Let \( D \) be \( O \)-minimal. Then the \( O \)-minimal dimension of a definable set \( X \subseteq D^* \) is the least \( n \) such that \( X \) admits a \( T_M \)-definable map into \( D^n \) with bounded finite fibers.

The Steinitz exchange principle states that if \( a \in \text{acl}(B \cup \{b\}) \) but \( a \notin \text{acl}(B) \), then \( b \in \text{acl}(B \cup \{a\}) \).

This holds for both strongly minimal and \( O \)-minimal structures, cf. [36].

For us the relevant \( O \)-minimal theory is \( DOAG \) itself. We will occasionally use stronger facts valid for this theory. Quantifier elimination for \( DOAG \) implies that
Lemma 3.1. (1) any parameterically definable function $f$ of one variable is piecewise affine; there exists a finite partition of the universe into intervals and points, such that on each interval $I$ in the partition, $f(x) = \alpha x + c$ for some rational $\alpha$ and some definable $c$.

(2) DOAG admits elimination of imaginaries.

Proof. (1) Follows from quantifier elimination for DOAG.

(2) It follows from (1) that any function definable with parameters in DOAG has a canonical code, consisting of the endpoints of the intervals of the coarsest such partition, together with a specification of the rationals $\alpha$ and the constants $c$. But from this it follows on general grounds that every definable set is coded (cf. [16] 3.2.2). So DOAG admits elimination of imaginaries. \qed

$C$-minimality. Let $T = T_{um}$ be the theory of ultrametric spaces, or equivalently chains of equivalence relations. (cf. [30].)

In more detail, $L$ has two sorts, $VF$ and $\Gamma$. The relations on $\Gamma$ are a constant $\infty$ and a binary relation $\prec$. In addition $L$ has a function symbol $VF^2 \to \Gamma$, written $\text{val}(x - y)$. $T$ states:

(1) $\Gamma_{\infty}$ is a dense linear ordering with no least element, but with a greatest element $\infty$.

(2) $\text{val}(x - y) = \infty$ iff $x = y$.

(3) $\text{val}(x - y) \geq \alpha$ is an equivalence relation; the classes are called closed $\alpha$-balls. Hence so is the relation $\text{val}(x - y) > \alpha$; whose classes are called open $\alpha$-balls.

(4) Let $\Gamma = \Gamma_{\infty} \setminus \{\infty\}$. For $\alpha \in \Gamma$, every closed $\alpha$-ball contains infinitely many open $\alpha$-balls.

A $T_{um}$-minimal theory will be said to be $C$-minimal. The notion considered in [15] is a little more general, but for theories $T_{um}$ they coincide. Since we will be interested in fields, this level of generality will suffice.

A theory $T$ extending $ACVF$ is $C$-minimal iff for any $M \models T$, every $T_M$-definable subset of $VF(M)$ is a Boolean combination of open balls, closed balls and points. If $T$ is $C$-minimal, $A \leq M \models T$, and $b$ is an $A$-definable ball, or an infinite intersection, let $p^b_A$ be the collection of $A$-definable sets not contained in a finite union of proper sub-balls of $b$. Then by $C$-minimality, $p^b_A$ is a complete type over $A$.

Let $T$ be $C$-minimal. Then in $T$, $\Gamma$ is $O$-minimal; and for any closed $\alpha$-ball $C$, the set of open $\alpha$-sub-balls of $C$ is strongly minimal. Denote it $C/(1+M)$. (These facts are immediate from the definition.)

Assume $T$ is $C$-minimal with a distinguished point $0$. We define: $\text{val}(x) = \text{val}(x - 0)$; $M = \{x : \text{val}(x) > 0\}$. Let $\mathcal{B}_\alpha$ be the family of all closed balls, including points. Among them are $\mathcal{B}_{d\alpha}(0) = \{x : \text{val}(x) \geq \alpha\}$. Let $RV = \bigcup_{\alpha \in \Gamma} B^\alpha(0)/(1+M)$, and let $rv : VF \setminus \{0\} \to RV$ and $\text{val}_\infty : RV \to \Gamma$ be the natural map. By an $rv$-ball we mean an open ball of the form $rv^{-1}(c)$.

The $T$-definable fibers of $\text{val}_\infty$ are referred to, collectively, as $RES_T$. Later we will fix a theory $T$, and write $RES$ for $RES_T$; we will also write $RES_A$ for $RES_{T_A}$. The unqualified notion “definable”, as well as many derived notions, will implicitly refer to $T$.

A certain notion of genericity plays an essential role in these theories.

Example 3.2. Let $T$ be a strongly minimal theory. For any $A \leq M \models T$, any $A$-definable set is finite or has finite complement. Therefore, the collection of co-finite sets forms a complete type. A realization of this type is called a generic element of $M$, over $A$.

Example 3.3. Let $T$ be an $O$-minimal theory. For any $A \leq M \models T$, any $A$-definable set contains, or is disjoint from, an infinite interval $(b, \infty)$ for some $b \in M$. The set of $A$-definable
sets containing such an interval is thus a complete type, the generic type of large elements of $T$.

Similarly, the set of $A$-definable sets containing an interval $(0, a)$ with $0 < a$ is the generic type of small positive elements. More generally, given a subset $S \subseteq A$ \( S' = \{ b \in A : (\forall s \in S)(s < b) \}$; then the definable sets $x > a(a \in S), x < b(b \in S')$ generate a complete type over $A$, called the type of elements just bigger than $S$.

Definition 3.4. Let $T$ be $C$-minimal. Let $b$ be a $T_A$-definable ball, or an infinite intersection of balls. The generic type $p_b$ of $b$ is defined by: $p_b|A' = p_b'$, for any $A \leq A' \leq M \models T$.

The completeness follows from $C$-minimality, since for any $A'$-definable subset $S$ of $b$, either $S$ is contained in a finite union of proper sub-balls of $b$, or else the complement $b \setminus S$ is contained in such a finite union.

A realization of $p_b|A'$ is said to be a generic point of $b$ over $A'$. An $A'$-definable set is said to be $b$-generic if it contains a generic point of $b$ over $A'$.

See §3.2 for some generalities about generic types. For our purposes it will suffice to consider generic types in one VF variable. For more information see [16] §2.5.

Remark 3.5. If $A = acl(A)$ then any type of a field element $tp(c/A)$ coincides with $p_b|A$, where $b$ is the intersection of all $A$-definable balls containing $c$.

This is intended to include the case of closed balls of valutative radius $\infty$, i.e., points; these are the algebraic types $x = c$. Note also the degenerate case that $c$ is not in any $A$-definable ball; then $b = VF$ and $tp(c/A)$ is the generic type of VF over $A$.

Not every generic $1$-type is of the form $p_b$ for a ball $b$ as above. For instance, let $b$ be an open ball, $c \in b$; then the generic type $p_b((x - c)^{-1})$ is not of this form.)

For V-minimal theories (defined below) it can be shown that every generic $1$-type is of the form $p_b$ or $p_b((x - c)^{-1})$.

Let $T$ be a $C$-minimal theory. Let $b$ be a definable ball, or an infinite intersection of definable balls. We say that $b$ is centered if it contains a proper definable finite union of balls. If $b$ is open, or a properly infinite intersection of balls, we have:

(*) If $b$ contains a proper finite union of balls, then it contains a definable closed ball (the smallest closed ball containing the finite set.)

For $C$-minimal fields of residue characteristic $0$, (*) is true of closed balls: the set of maximal open sub-balls of $b$ forms an affine space over the residue field $k$, where the center of mass of a finite set is well-defined.

Clearly $b$ is centered over $acl(A)$ if and only if it is centered over $A$. The term “centered” will be justified to some extent by the assertion of Lemma 3.39, that when $A$ is generated by elements of $VF \cup RV \cup I$, any $A$-definable closed ball contains an $A$-definable point, and thus a centered ball has a definable “center”.

Lemma 3.6. $b$ is centered over $A$ iff $b$ is not transitive over $A$.

This is immediate from the definition, and from $C$-minimality, since any proper definable subset would have to be a Boolean combination of balls.

An often useful corollary of $C$-minimality:

Lemma 3.7. Let $T$ be $C$-minimal, $X$ a definable subset of $VF$, and $Y$ a definable set of disjoint balls. Then for all but finitely many $b \in Y$, either $b \subseteq X$ or $b \cap X = \emptyset$.

Proof. $X$ is a finite Boolean combination of balls, so it suffices to prove this when $X$ is a ball; then $X$ is contained in at most one ball $b \in Y$; for any other $b \in Y$, either $b \subseteq X$ or $b \cap X = \emptyset$. \hfill \Box

Lemma 3.8. Let $(b_t : t \in Q)$ be a definable family of pairwise disjoint balls. Then for any nonalgebraic $t \in Q$, $b_t$ is transitive over $< t$.
Proof. Consider a definable $R' \subseteq Q \times VF$ with $R'(t) \subseteq b_t$. Let $Y = \bigcup_{t \in Q} R'(t)$. Then $Y$ is a definable subset of $VF$, hence a finite combination of a finite set $H$ of balls. The $b_t$ are pairwise disjoint, so at most finitely many can contain an element of $H$; and thus no nonalgebraic $b_t$ contains an element of $H$. Thus each ball in $H$ is disjoint from, or contains, any given $b_t$. It follows that $Y$ is disjoint from, or contains, any given $b_t$. Thus $b_t \cap Y$ cannot be a non-empty proper subset of $b_t$. □

**Internalizing finite sets.** The following lemma will be generalized later to finite sets of balls. It is of such fundamental importance in this paper that we include it separately in its simplest form. The failure of this lemma in residue characteristic $p > 0$ is the main reason for the failure of the entire theory to generalize, in its present form. Recall the definition of $RV$, §2.1.

**Lemma 3.9.** Let $T$ be a $C$-minimal theory of fields of residue characteristic $0$ (possibly with additional structure), $A \leq M \models T$. Let $F$ be a finite $T_A$-definable subset of $VF^n$. Then there exists $F' \subseteq RV^n$, and a $T_A$-definable bijection $h : F \to F'$.

**Proof.** First consider $F = \{c_1, \ldots, c_n\} \subseteq VF$. Let $c = (\sum_{i=1}^n c_i)/n$ be the average; then $F$ is $T_A$-definably isomorphic to $\{c_1 - c, \ldots, c_n - c\}$. Thus we may assume the average is 0. If there is no nontrivial $A$-definable equivalence relation on $F$, then $\text{val}(x - y) = \alpha$ is constant on $x \neq y \in F$. In this case rv is injective on $F$ and one can take $h = \text{rv}$. Otherwise, let $E$ be a nontrivial $A$-definable equivalence relation on $F$. By an $E$-symmetric polynomial, we mean a polynomial $H(x_1, \ldots, x_n)$ with coefficients in $A$, invariant under the symmetric group on each $E$-class. For any such $H$, $H(F)$ is a $T_A$-definable set with $< n$ elements. There exists $H$ such that $H(F)$ has more than one element. By induction, there exists an injective $A$-definable function $h_0 : H(F) \to RV^n$. Let $h_1 = h_0 \circ H$. For $d \in h_0(H(F))$, and $d' = h_0^{-1} d$, let $F_d = H^{-1} h_0^{-1} (d) = H^{-1} (d')$. By induction again, there exists an $A(d) = A(d')$-definable injective function $g_d : F_d \to RV^n$. (We can take the same $m'$ for all $d$.) Define $h(x) = (h_1(x), g_{h_1(x)}(x))$. Then clearly $h$ is $A$-definable and injective.

The case $F \subseteq VF^n$ follows using a similar induction, or by finding a linear projection with $\mathbb{Q}$-coefficients $VF^n \to VF$ which is injective on $F$. □

3.1. **Basic geography of $C$-minimal structures.** Let $T$ be a $C$-minimal theory. We begin with a rough study of the existence and non-existence of definable maps between various regions of the structure: $K, \Gamma, RV, VF$ and $VF/\emptyset$.

We will occasionally refer to *stable* definable sets.

A definable set $D$ of a theory $T$ is called stable if there is no model $M \models T$ and $M$-definable relation $R \subseteq D^2$ and infinite subset $J \subseteq M(D)$ such that $R \cap J^2$ is a linear ordering. This is a model-theoretic finiteness condition, greatly generalizing finite Morley rank, and in turn strong minimality (cf. [28]).

It is shown in [16], that a definable subset of ACVF $^+_K$ is stable if and only if it has finite Morley rank, if an only if it admits no parametrically definable map onto an interval of $\Gamma$; and this is if and only it embeds, definably over acl($A$), into a finite dimensional $K$-vector space. These vector spaces have the general form $\Lambda / M\Lambda$, with $\Lambda \leq VF^n$ a lattice. Within the sorts we are using here, the relevant ones are the finite products of vector spaces of RES. More generally in a $C$-minimal structure with sorts $VF, RV$, all stable sets are definably embeddable (with parameters) into RES. We will however make no use of these facts, beyond justifying the terminology. Thus “$X$ is a stable definable set” can simply be read as “there exists a definable bijection between $X$ and a subset of RES”.

The first fact is the unrelatedness of $K$ and $\Gamma$. 
Lemma 3.10. Let $Y$ be a stable definable set. Then $Y, \Gamma$ are strongly orthogonal. In particular, any definable map from $Y$ to $\Gamma$ has finite image.

Proof. We prove the second statement first: let $M \models T$. Let $f : Y \to \Gamma$ be an $M$-definable map. Then $f(Y)$ is stable, and linearly ordered by $<_\Gamma$; hence by definition of stability it is finite.

Let $\gamma = (\gamma_1, \ldots, \gamma_n) \in \Gamma$. We have to show that for a $Y$-generated structure $A$, $tp(\gamma)$ implies $tp(\gamma/A)$. It suffices to show that for any $a_1, \ldots, a_n \in A$, $tp(\gamma_i/ < \gamma_1, \ldots, \gamma_1, a_1, \ldots, a_n >)$, for each $i$. By passing to $T_{<\gamma_1, \ldots, \gamma_i-1}$ we may assume $m = 1, \gamma \in \Gamma$. Similarly we may assume $n = 1$; let $a = a_1 \in Y$. To show that $tp(\gamma)$ implies $tp(\gamma/a)$, it suffices to show that any $T_\gamma$-definable subset of $\Gamma$ is definable. By O-minimality, any $T_\gamma$-definable subset of $\Gamma$ is a finite union of intervals, so (in view of the linear ordering) it suffices to show this for intervals $(c_1, c_2)$. But if the interval is $T_\gamma$-definable then so are the endpoints, so $c_i = c_1(a)$ is a value of a definable map $Y \to \Gamma$. But such maps have finite images, so $c_i$ lies in a finite definable set. Using the linear ordering, we see that $c_i$ itself is definable, and hence so is the interval. \qed

Lemma 3.11. There are no definable sections of $val_\gamma : RV \to \Gamma$ over an infinite subset of $\Gamma$. In fact if $Y \subset RV^n$ is definable and $val_\gamma$ is finite-to-one on $Y$, then $Y$ is finite.

Proof. Looking at the fibers of the projection of $Y$ to $RV^{n-1}$, and using induction, we reduce the lemma to the case $n = 1$. In this case, by Lemma 3.7, every definable set is a Boolean combination of pullbacks by $val_\gamma$ of subsets of $\Gamma$, and finite sets. \qed

Lemma 3.12. Let $M \models T$ and let $Y \subset \mathcal{B}_0^n$ be an infinite definable set. Then there exists a surjective $M$-definable map of $Y$ to a proper interval in $\Gamma$.

Proof. Since $\Gamma$ is O-minimal, any infinite $M$-definable subset contains a proper interval. Thus it suffices to find an $M$-definable map of $Y$ onto an infinite subset of $\Gamma$.

If the projection of $Y$ to $\mathcal{B}_0^{n-1}$ as well as every fiber of this projection are finite, then $Y$ is finite. Otherwise, replacing $Y$ by one of the fibers or by the projection, we reduce inductively to the case $n = 1$.

Let $v(y) \in \Gamma$ be the valuative radius of the ball $y$. Then $v(Y)$ is an $M$-definable subset of $\Gamma$. If it is infinite, we are done; otherwise we may assume all elements of $Y$ have the same valuative radius $\gamma$.

Let $W = \bigcup \text{val}$. By C-minimality, $W$ is a Boolean combination of balls $b_i$ (open, of valuative radius $< \gamma$, or closed, of valuative radii $\delta_i \leq \gamma$). If $W$ contains some $W' = b_i \setminus \left(b_j \cup \cdots \cup b_k\right)$, where $b_j$ is a proper sub-ball of $b_i$, and $\delta_i < \gamma$, pick a point $c$ in $W'$; then for any $\delta$ with $\gamma$ there exists $\epsilon \in W'$ with $\text{val}(c - \epsilon) = \delta$. It follows that the balls $b_j(c), b_j(c')$ of radius $\gamma$ around $c, c'$ are both in $Y$; but infinitely many such $\delta$ exist; fixing $c$, we obtain a map $\beta_\gamma(c') \to \text{val}(c - c')$ into an infinite subset of $\Gamma$.

Otherwise, $W$ can only be a finite set of balls of valuative radius $\gamma$. So $Y$ is finite. \qed

Corollary 3.13. $\mathcal{B}_0^n$ contains no stable definable set. In particular VF contains no strongly minimal set.

By contrast,

Proof. By Lemma 3.11, the inverse image of some point in $\Gamma^n$ must be infinite. \qed
Lemma 3.15. Let $M \models T$. Let $Y \subseteq \mathbb{B}_{\mathfrak{c}_3}$ be a definable set. Let $\text{rad}(y)$ be the valuate radius of the ball $y$. Then either $\text{rad} : Y \rightarrow \Gamma$ is finite-to-one, or else there exists an $M$-definable map of an $M$-definable $Y' \subseteq Y$ onto a strongly minimal set.

Proof. If $\text{rad}$ is not finite-to-one, then $Y$ contains an infinite set $Y'$ of balls of the same radius $\alpha$. Then $\text{rad}(Y')$ contains a closed ball $b$ of valuate radius $\beta < \alpha$. The set $S$ of open sub-balls $b'$ of $b$ of valuate radius $\beta$ forms a strongly minimal set; the map sending $y \in Y'$ to the unique $b' \in S$ containing $y$ is surjective. \hfill $\square$

The following lemma regarding $\text{VF}/\mathcal{O}$ will be needed for integration with an additive character (§11).

Lemma 3.16. Let $Y$ be a stable definable set, $Z \subseteq \text{VF} \times Y$ a definable set such that for $y \in Y$, $Z(y) = \{x : (x, y) \in Z\}$ is additively $M$ invariant. Then for all but finitely many $\mathcal{O}$-cosets $C$, $Z \cap (C \times Y')$ is a rectangle $C \times Y'$.

Proof. For $y \in Y$, $Z(y)$ is a $T_y$-definable subset of $\text{VF}$, hence a Boolean combination of a finite $< y >$-definable set of balls $b_1(y), \ldots, b_k(y)$. Let $B_i(y)$ be the smallest closed ball containing $b_i(y)$. According to Lemma 3.13, since the set of closed balls occurring as $B_i(y)$ for some $y$ is stable, it is finite:

$$\{B_i(y) : y \in Y\} = \{B_1, \ldots, B_k\}$$

All the $B_i$ are $\mathcal{O}$-invariant. Let $R$ be the set of $\mathcal{O}$-cosets $C$ that are equal to some $B_i$.

If $B_i(y)$ has valuate radius $< 0$ (i.e. it is bigger than an $\mathcal{O}$-coset), then so is $b_i(y)$, so the characteristic function of such a $b_i(y)$ is constant on any closed $\mathcal{O}$-coset $C$. If $C \notin R$, then it is disjoint from any $B_i$ of valuate radius equal to (or greater than) $0$, so the characteristic functions of the corresponding $b_i(y)$ are also constant on it. Thus with finitely many exceptional $C$, any such characteristic function is constant on $C$, and the claim follows. \hfill $\square$

3.2. Generic types and orthogonality. Two generic types $p, q$ are said to be orthogonal if for any base $A'$, if $c \models p|A'$, $d \models q|A'$, then $p$ generates a complete type over $A(d)$, equivalently $q$ generates a complete type over $A(c)$. We will see that generics of different kinds are orthogonal (cf. Lemma 3.19). This orthogonality of types is weaker than the orthogonality of definable sets mentioned in the introduction, and in the present case is only an indirect consequence of the orthogonality between the residue field and value group; these types do not have orthogonal definable neighborhoods.

If $\gamma \in \Gamma$ and $rk\mathcal{O}(\Gamma(C(a))/\Gamma(C)) = n$, we say that $tp(\gamma/C)$ has $\Gamma$-dimension $n$.

Lemma 3.17. Let $p_{\Gamma}$ be a $T_{A'}$-type of elements of $\Gamma^n$ of $\Gamma$-dimension $n$. Let $P = \text{val}^{-1}(p_{\Gamma})$. Then

1. $\text{val}^{-1}(p_{\Gamma})$ is a complete type over $A$. In other words, for any $A$-definable set $X$, either $\text{val}^{-1}(p_{\Gamma}) \subseteq X$ or $\text{val}^{-1}(p_{\Gamma}) \cap X = \emptyset$.
2. If $D$ is a stable $A$-definable set and $d_1, \ldots, d_n \in D$, then $P$ implies a complete type over $A(d_1, \ldots, d_n)$.
3. If $c \in P$ then $D(A(c)) = D(A)$.
4. $P$ is complete over $A$.

Proof. (1) reduces inductively to the case $n = 1$. Since $\text{val}^{-1}(p_{\Gamma})$ is a disjoint union of open balls, (1) for $n = 1$ follows from Lemma 3.7: an $A$-definable set $X$ cannot intersect nontrivially each of an infinite family of open balls. Therefore either $X$ is disjoint from almost all, or $X$
contains almost all open balls \( \text{val}^{-1}(c) \), \( c \models p_T \); in the former case the complement of \( X \) contains \( \text{val}^{-1}(p_T) \), and in the latter \( X \) contains \( \text{val}^{-1}(p_T) \) since \( p_T \) is complete.

(2) By strong orthogonality, \( p_T \) generates a complete type \( q' \) over \( A(d) \), of \( \Gamma \)-dimension \( n \).

By (1) over \( A(d) \), \( \text{val}^{-1}(p_T) \) is complete over \( A(d) \). But if \( c \in P \) then \( \text{val}(c) \models p_T \) so \( c \in \text{val}^{-1}(p_T) \). Thus \( P \) implies a complete type over \( A(d) \).

(3) follows from (2): if \( d \in D(A(c)) \) then there exists a formula \( \phi \) such that \( \models \phi(d, c) \) and such that \( \phi(x, c) \) has a unique solution. By (2) \( \phi \) is a consequence of \( P(c) \cup tp(d/A) \), and hence by compactness of a formula \( \phi_1(x) \land \phi_2(c) \) where \( \phi_2 \in tp(d/A) \). So already \( \phi_1(x) \) has the unique solution \( d \), and thus \( d \in D(A) \).

(4) is immediate from (1).

\[ \square \]

**Lemma 3.18.** Let \( q \) be a \( T_A \)-type of elements of \( \text{RES}^\Gamma_{A} \) of \( \text{RES} \)-dimension \( n \). Let \( Q = \text{rv}^{-1}(q) \). Then \( Q \) is complete over \( A \). Moreover, if \( \gamma_1, \ldots, \gamma_m \in \Gamma \) then \( Q \) implies a complete type over \( A(\gamma_1, \ldots, \gamma_m) \).

**Proof.** Again the lemma reduces inductively to the case \( n = 1 \), and for \( n = 1 \) follows from Lemma 3.7, since \( \text{val}^{-1}(q) \) is a union of disjoint annuli; the “moreover” also follows from orthogonality as in the proof of Lemma 3.17 (2).

\[ \square \]

**Lemma 3.19 (\cite{16} §2.5).** (1) If \( b \) is an open ball, or a properly infinite intersection of balls, and \( b' \) a closed ball, then \( p_b, p_{b'} \) are orthogonal.

(2) Any \( b \)-definable map to \( k \) is constant on \( b \) away from a proper sub-ball of \( b \).

**Proof.** We recall the proof from \cite{16} §2.5: The statement becomes stronger if the base set is enlarged. Thus we may assume that \( b \) and \( b' \) are centered; by translating we may assume both are centered at 0, and by a multiplicative renormalization that \( b' \) is the unit closed ball. So

\[ (*) \quad c \models p_{b'}(A) \text{ iff } c \in 0 \text{ and } \text{res}(c) \notin \text{acl}(A). \]

On the other hand let \( p_T \) be the type of elements of \( \Gamma \) that are just bigger than the valuative radius of \( b \) (cf. Example 3.3). Then \( d \models p_b \text{ iff } \text{val}(d) \models p_T \), i.e. \( p_b \) is now the type \( p_T \) described in Lemma 3.17. By Lemma 3.17, if \( c' \in P \) then \( k(A(c')) = k(A) \). It follows that if \( c \models p_{b'}(A) \) then \( \text{res}(c) \notin \text{acl}(k(A(c'))) \). By (\( \ast \)) \( c \models p_{b'}(A(c')). \)

For the second statement, let \( g \) be a definable map \( b \to k \); by Lemma 3.17 (3), \( g \) is constant on the generic type of \( b \); by compactness, \( g \) is constant on \( b \) away from some proper sub-ball of \( b \).

\[ \square \]

**Lemma 3.20.** Let \( a = (a_1, \ldots, a_n) \in \text{RV}^n \), and assume \( a_i \notin \text{acl}(A(a_1, \ldots, a_{i-1})) \) for \( 1 \leq i \leq n \). Then the formula \( D(x) = \bigwedge_{i=1}^{n} \text{rv}(x_i) = a_i \) generates a complete type over \( A(a) \), and indeed over any \( \text{RV} \cup \Gamma \)-generated structure \( A' \) over \( A \).

In particular, if \( q = tp(a/A) \), any \( A \)-definable function \( f : \text{rv}^{-1}(q) \to \text{RV} \cup \Gamma \)-factors through \( \text{rv}(x) = (\text{rv}(x_1), \ldots, \text{rv}(x_n)) \).

**Proof.** This reduces inductively to the case \( n = 1 \). If we replace \( A \) by a bigger set \( M \) (such that \( a_i \notin \text{acl}(A(a_1, \ldots, a_{i-1})) \) for \( 1 \leq i \leq n \)), the assertion becomes stronger; so we may assume \( A = M \models T \). Let \( \text{rv}(c) = \text{rv}(c') = a \). Either \( \text{val}(c) = \text{val}(c') \notin M \), or else \( \text{val}(c) = \text{val}(c') = \text{val}(d) \) for some \( d \in M \), and \( \text{res}(c/d) = \text{res}(c'/d) \notin M \); in either case, by Lemma 3.17 or Lemma 3.18, we have \( tp(c/M) = tp(c'/M) \). So \( tp(c, \text{rv}(c)/M) = tp(c, \text{rv}(c'/M)) \), i.e.\( tp(c/M(a)) = tp(c'/M(a)) \). This proves completeness over \( A(a) \).

Let \( A' \) be a structure generated over \( A \) by finitely many elements of \( \Gamma \). Then \( A'(a) = A(\gamma_1, \ldots, \gamma_k, a) \), where \( \gamma_i \in \Gamma \), and \( \gamma_i \notin A(\gamma_1, \ldots, \gamma_{i-1}, \text{val}(a)) \). It follows that \( \text{rv}(a) \notin A(\gamma_1, \ldots, \gamma_k) \), so \( D(x) \) generates a complete type over \( A(\gamma_1, \ldots, \gamma_k)(a) = A'(a) \).
Let $A''$ be generated over $A'(a)$ by elements of stable $A$-definable sets. Since $D(x)$ is the (unique, and therefore) generic type of an open ball over $A'(a)$, by Lemma 3.17, it generates a complete type over $A''$.

Now if $A'' = A(\gamma_1, \ldots, \gamma_k, r_1, \ldots, r_n, d)$ where $\gamma_2 \in \Gamma$, $r_i \in RV$ and $d$ lies in a stable set over $A$, let $A' = A(\gamma_1, \ldots, \gamma_k, \text{val}_v(r_1), \ldots, \text{val}_v(r_n))$; then $A'/A$ is $\Gamma$-generated, and $A''/A$ is generated by elements of stable sets (including $\text{val}_v^{-1}(r_i)$). Thus the above applies.

The last statement follows by applying the first part of the lemma over $A'' = A(f(c))$: the formula $f(x) = f(c)$ must follow from the formula $D(x)$, since $D(x)$ generates a complete type over $A''$.

3.3. Definable sets in group extensions. We will analyze the structure of RV in a slightly more abstract setting. In the following lemmas we assume $R$ is a ring, and $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ is a definable exact sequence of $R$-modules in $T$. This means that $A, B, C$ are definable sets, and that one is also given definable maps $+_A : A^2 \rightarrow A, f^A_\theta : A \rightarrow A$ for each $r \in R$, and similarly for $B, C$; and definable maps $\iota : A \rightarrow B, \theta : B \rightarrow C$, such that in any $M \models T$, $A(M), B(M), C(M)$ are $R$-modules under the corresponding functions, and $0 \rightarrow A(M) \rightarrow B(M) \rightarrow C(M) \rightarrow 0$ is an exact sequence of homomorphisms of $R$-modules.

**Lemma 3.21.** Consider a theory with a sequence $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ of definable $R$-modules and homomorphisms (carrying additional structure.) Assume:

1. $A, C$ are stably embedded and orthogonal.
2. Every almost definable subgroup of $A^n$ is defined by finitely many $R$-linear equations.
3. (“No definable quasi-sections.”) If $P$ is a definable subset of $B^n$ whose projection to $C^n$ is finite-to-one, then $P$ is finite.

Then every almost definable subset $Z$ of $B^n$ is a finite union of sets of the form

$$\{b : \theta(b) \in W,Nb \in Y\}$$

where $N \in B_{n,k}(R)$ is an $n \times k$ matrix, $X$ is an almost definable subset of a single coset of $A^k$, $W$ is an almost definable subset of $C^n$.

**Note:**

1. To verify (3), it suffices to check it for $n = 1$ but for parametrically definable $P$.
2. If $C$ is definably linearly ordered, and $Z$ is definable, then $Y, W$ may be taken definable.

**Proof.** Using a base change as in §2.1.4, we may assume almost definable sets are definable. Replacing $B$ by $B^n$ and $R$ by $M_n(R)$, we may assume $n = 1$. Let $Z$ be a definable subset of $B$. Given $X \in A$, let $[X]$ denote the class of $X$ up to translation; so $[X] = [X']$ if $X = X' + a$ for some $a \in A$. Now a definable subset $U$ of a coset $b + A$ of $A$ has the form $b + X, X \in A$; the class $[X]$ is well-defined, and we will denote $[U] = [X]$. We obtain a map

$$c \mapsto [Z \cap \theta^{-1}(c)]$$

In more detail: for any $b \in (\theta^{-1}(c) \cap Z)$, we have $(\theta^{-1}(c) \cap Z) - b \subseteq A$, and so by stable embeddedness of $A$ we can write $(\theta^{-1}(c) \cap Z) - b = X(a)$ for some $a \in A^m$. The tuple $a$ is not well-defined; but the class of $a$ in the definable equivalence relation:

$$x \sim x' \iff (\exists t \in A)((t + X(x)) = X(x'))$$

is obviously a function of $c$ alone. By the orthogonality assumption, this map is piecewise constant. So we may assume it is constant, and fix $C_0$ with $[Z \cap \theta^{-1}(c)] = [C_0]$. Let $S$ be the stabilizer $S = \{a \in A : a + C_0 = C_0\}$. Then for $a \in S$, $a + (Z \cap \theta^{-1}(c)) = (Z \cap \theta^{-1}(c))$ for any $c \in C$, so that also $S = \{a \in A : a + Z = Z\}$, and $S$ is definable.
Now $Z \cap \vartheta^{-1}(c) = C_0 + f(c)$ for some $f(c) \in \vartheta^{-1}(c)$; $f(c) + S$ is well-defined.

By assumption (2), $S = \text{Ker}(r_1) \cap \ldots \cap \text{Ker}(r_m)$ for some $r_i \in R$. Let $I = \{r_1, \ldots, r_m \}$. For $r \in I$, $f_r(c) := rf(c)$ is a well-defined element of $B$, and for all $c \in \vartheta(Z)$, $r(Z \cap \vartheta^{-1}(c)) = rC_0 + f_r(c)$.

We have $\vartheta f_r(c) = rc$. If $d \in \text{Ker}(r : C \to C)$, then $f_r(d + c) = rc$ also, so $f_r(d + c) - f_r(c) \in A$. By orthogonality, for fixed $r$, $f_r(d + c) - f_r(c)$ takes finitely many values as $c, d$ vary in $C$. In other words, $\{rf(c) : c \in \vartheta(Z)\}$ is a quasi-section above $r\vartheta(Z)$. By (3), $r\vartheta(Z)$ is finite, for each $r \in I$. Let $N = (r_1, \ldots, r_m)$, $Y' = N \vartheta$. Then $\vartheta(Y')$ is finite. It follows that $Y'$ is contained in a finite union of cosets of $A$, so $C, Y'$ are orthogonal.

Thus $\{(\vartheta(z), N\vartheta) : z \in Z\}$ is a finite union of rectangles; upon dividing $Z$ further, we may assume this set is a rectangle $W \times Y$. Now if $\vartheta(b) \in W$ and $Nb \in Y$ then for some $z \in Z$, $\vartheta(b) = \vartheta(z)$ and $Nb = Nz$; it follows that $b - z \in A$ and $b - z \in S$; so $b \in S + Z = Z$. Thus $Z$ is of the required form.

**Corollary 3.22.** $T$ be a complete theory in a language $L$ satisfying the assumptions of Lemma 3.21. Let $L \subseteq L', T \subseteq T'$, and assume (1)-(3) persist to $T'$. If $T, T'$ induce the same structure on $A$ and on $C$, up to constants they induce the same structure on $B$, i.e. every $T$-definable subset of $B^*$ is parametrically $T'$-definable.

**Proof.** Apply Lemma 3.21 to $T'$, and note that every definable set in the normal form obtained there is already parametrically definable in $T$. \qed

We will explicitly use imaginaries in $\text{RV}$ only rarely; but our ability to work with $\text{RV}$, using $\Gamma$ as an auxiliary, is partly explained by:

**Corollary 3.23.** Let $0 \to A \to B \to C \to 0$ be as in Lemma 3.21, and assume $C$ carries a definable linear ordering. Let $\bar{V}$ be the disjoint union of the definable cosets of $A$ in $B$, with structure induced from $T$. Let $e$ be an imaginary element of $B$. Then $< e > = < (a', c') >$ for some pair $(a', c')$ consisting of an imaginary of $\bar{V}$ and an imaginary of $C$. Thus if $\bar{V}, C$ eliminate imaginaries, so does $B \cup C \cup \bar{V}$.

**Proof.** Let $e$ be an imaginary element of $B$; let $E_0$ be the set of $A, \bar{V}$-imaginaries that are algebraic over $e$.

By Lemma 3.21, applied to a definable set with code $e$ in the theory $T_{E_0}$, there exist almost definable subsets of $\bar{V}, C^m$ from which $e$ can be defined. These are coded by imaginaries permitted in the definition of $E_0$. Thus $e$ is $E_0$-definable. So $e = g(d)$ for some definable function $g$ and some tuple $d$ from $E_0$. Let us now show that $e$ is equi-definable with a finite set, i.e. an imaginary of the form $(f_1, \ldots, f_n) / \text{Sym}(n)$. Let $W$ be the set of elements with the same type as $d$ over $\Gamma$; $W$ is finite by definition of $E_0$, and is $e$-definable. But $e = g(w)$ for any element $w \in W$, so $e$ is definable from $\{W\}$.

It remains to see that every finite set of elements of $E_0$ is coded by imaginaries of $A$ and $C$ and elements of $B$. Since $C$ is linearly ordered, it suffices to consider finite sets whose image in $C^m$ consists of one point. These are subsets of some definable coset of $A^m$, so again by elimination of imaginaries there they are coded. \qed

**Corollary 3.24.** The structure induced on $\text{RV} \cup \Gamma$ from $\text{ACVF}$ eliminates imaginaries.

**Proof.** $\Gamma_{E_0}$ eliminates imaginaries, and so does $\text{ACVF}$ (c.f. [30]). Note that $\bar{V}$ is essentially a family of 1-dimensional $k$-vector spaces, closed under tensor products and roots and duals. Hence by [18], $\bar{V}_{E_0}$ eliminates imaginaries too. Our only application of this lemma will be in a situation when parameters can be freely added; in this case, it suffices to quote elimination of imaginaries in $\text{ACVF}$. \qed
Corollary 3.25. Let $T$ be a theory as in Lemma 3.21, with $R = \mathbb{Z}$, and $C$ a linearly ordered group. Then every definable subset of $B^n$ is a disjoint union of $GL_n(\mathbb{Z})$-images of products $Y \times \vartheta^{-1}(Z)$, with $|Y| = 1$. In particular the Grothendieck semiring $K_+(B)$ (with respect to the category of all definable sets and functions of $B$) is generated by the classes of elements $Y \subset B^n$ with $|\vartheta Y| = 1$, and pullbacks $\vartheta^{-1}(Z)$, $Z \subset C^m$.

Proof. By Lemma 3.21, the Grothendieck ring is generated by classes of sets $X$ of the form $X = \{b \in B^n : \vartheta(b) \in W, Nb \in Y\}$. After performing row and column operations on the matrix $N$, we may assume it is the composition of a projection $p : R^n \to R^k$ with a diagonal $k \times k$ integer matrix with nonzero determinant. The composition $\vartheta p(X)$ is finite; since $C$ is ordered, each element of $\vartheta p(X)$ is definable, and so we may assume $\vartheta p(X)$ has one element $e$. Thus $W = \{(e) \times W'\}$ for some $W'$, and $X = pX \times \vartheta^{-1}(W')$. □

Lemma 3.26. Let $T$ be a theory, and let $0 \to A \to B \to C \to 0$ be an exact sequence of $f$ of definable Abelian groups and homomorphisms. If $E \leq M \models T$, we will write $E_A = A(E)$, etc.

Assume:

1. $A, C$ are orthogonal.
2. Any parametrically definable subset of $B$ is a Boolean combination of sets $Y$ with $\vartheta(Y)$ finite, and of full pullbacks $\vartheta^{-1}(Z)$.
3. $C$ a uniquely divisible Abelian group, and for any $E \leq M \models T$, every divisible subgroup $E_C$ is algebraically closed in $C$ over $E$.
4. For any prime $p > 0$, $T \models (\exists x \in A)(px = 0, x \neq 0)$

Let $Z \subset C^n$ and $f : Z \to C$ be definable, and suppose there exists an $E$ and $E$-definable $X \subset B^n$ and $F : X \to B$ lifting $f$; $\vartheta X = Z, \vartheta F(x) = f(\vartheta x)$. Then there exists a partition of $Z$ to finitely many definable sets $Z_\nu$, such that for each $\nu$, for some $m \in Z^n$, $f(x) - \sum_{i=1}^n m_i x_i$ is constant on $Z_\nu$.

The main point is the integrality of the coefficients $m_i$.

Proof. It suffices to show that for any $M \models T$ and any $c = (c_1, \ldots, c_n) \in Z(M)$, there exists $m = (m_1, \ldots, m_n) \in Z$ such that $f(c) - mc \in E^0$, where $E^0 = dcl(\emptyset)$ is the smallest substructure of $M$. For if so, there exists a formula of one variable of sort $C$, such that $T \models (\exists z \in Z)\psi(z)$, $M \models \psi(f(c) - mc)$. By compactness there exists a finite set $F$ of such pairs $\nu = (m, \psi)$, such that for any $M \models T$ and $c \in Z(M)$, for some $(m, \psi) \in F$, $M \models \psi(f(c) - mc)$; the required partition is given by $Z_m, \psi = \{z \in Z : \psi(f(z) - m z)\}$.

Fix $M$ and $c \in Z(M)$. Let $< c >$ be the smallest divisible subgroup of $C(M)$ containing $E^0_C$ and $c_1, \ldots, c_n$. By (3), $< c >$ is closed under $f$, so $f(c) \in < c >$, i.e. $f(c) = \sum \alpha_i c_i + d$ for some $\alpha_i \in \mathbb{Q}$ and some $d \in E^0_C$. The only problem is to show that we can take $\alpha_i \in \mathbb{Z}$.

We will use induction on $n$. Let $K = \{\beta \in \mathbb{Q}^n : \beta \cdot c \in E^0_C\}$. $K$ is a $\mathbb{Q}$-subspace of $\mathbb{Q}^n$. If $K \neq (0)$, there exists a primitive integral vector $\beta_1 \in K$. $\beta_1$ may be completed to a basis for a $\mathbb{Z}$-lattice in $\mathbb{Q}^n$. Applying a $GL_n(\mathbb{Z})$ change of variables to $B^n$, we may assume $\beta_1 = (1, 0, \ldots, 0)$, i.e. $c_1 \in E^0_C$. But then let $f'(z_2, \ldots, z_n) = f(c_1, z_2, \ldots, z_n)$. Then $f'$ lifts to a definable function on $B^n$ (with parameters, of the form $F(b_1, y_2, \ldots, y_n)$) so by induction, $f(c_1, \ldots, c_n) = f'(c_2, \ldots, c_n) = \sum_{i \geq 2} m_i z_i + d'$ for some $m_2, \ldots, m_n \in \mathbb{Z}$ and $d' \in E^0_C$, as required.

Thus we can assume $K = (0)$.

We can find $m_i, m_i \in \mathbb{Z}, e \in dcl(\emptyset)$ with

$$mf(c) = \sum m_i c_i + e$$
If \( \textstyle m \mid m_i \) we are done. We will now derive a contradiction from the contrary assumption that \( m \) does not divide each \( m_i \) in such an equation, with \( f \) a liftable function. We may assume that the greatest common divisor of \( m,m_1,\ldots,m_n \); so there exists a prime dividing \( m \) but not (say) \( m_1 \).

Let \( g(x) = f(x,c_2,\ldots,c_n) - e/m - \sum_{i=2}^{n} m_i c_i/m \); then \( mg(c_1) = m_1 c_1 \), \( m \) does not divide \( m_1 \), \( g \) is \( E = \text{acl}(c_2,\ldots,c_n) \)-definable and liftable. Since \( K = (0) \), by assumption (3), \( c_1 \notin \text{acl}(E) \).

Let \( E' \supseteq E \) be such that \( g \) lifts to an \( E' \)-definable function \( G' \). Enlarging the model if necessary, let \( c_1' \) realize \( \text{tp}(c_1/E) \), with \( c_1' \notin E' \) (cf. Example 2.4). Therefore there exists \( E'' \) such that \( E'', c_1' \) and \( E', c_1' \) have the same type. In particular \( g \) lifts to an \( E'' \)-definable function \( G' \).

Consider any \( b_i \) such that \( \vartheta(b_i) = c_1 \). Then \( m \vartheta G(b_i) - m_1 \vartheta(b_i) = 0 \). So \( m \vartheta G(b_1) - m_1 b_1 \in A \).

Let \( p \) be prime, \( p \mid m \) but \( p \nmid m_1 \). Let \( s, r \in \mathbb{Z} \) be such that \( sp - rm_1 = 1 \), and let \( h(x) = sx - \frac{rm}{p} g(x) \). Then \( \varphi(c_1) = ps c_1 - rm g(c_1) = ps c_1 - rm_1 c_1 = c_1 \). Also \( h \) is liftable over \( E'' \); indeed if \( G \) is \( E'' \)-definable and lifts \( g \), then \( H(x) = sx - \frac{rm}{p} G(x) \) lifts \( h \).

So \( p h(b_1) = b_1 + d \), some \( d \in A \). Let \( b_2 = H(b_1) \); then \( b_1 = pb_2 - d \), or \( b_2 = H(pb_2 - d) \).

Now let \( c_2 = h(c_1) = \vartheta(b_2) \). Then \( p c_2 = c_1 \), and so \( c_2 \notin \text{acl}(E'') \), since by unique divisibility \( c_1 \in \text{acl}(h(c_1)) \). By (1), \( c_2 \notin \text{acl}(E''(d)) \). Let \( C_2 = \vartheta^{-1} c_2 \). By (2), any \( E''(d) \)-definable set either contains \( C_2 \) or is disjoint from \( C_2 \). Hence for any \( y \in C_2 \), \( y = H(py - d) \).

By (4) there exists \( 0 \neq \omega_p \in A \) with \( pw_p = 0 \). Let \( b'_2 = b_2 + \omega_p \). Then \( b_2 \in C_2 \), so \( b_2 = H(pb_2 - d) \). But \( pb_2 = pb_2 \), so \( b_2 = b'_2 \) and \( \omega_p = 0 \), a contradiction. \( \Box \)

**Remark 3.27.**

(1) It follows from Lemma 3.26 that a definable bijection between subsets of \( C^n \) that lifts to subsets of \( B^n \) is piecewise given by an element of \( \text{GL}_n(\mathbb{Z}) \times C^n \). (cf. Lemma 3.28.)

(2) The assumption (4) on torsion does not hold in characteristic \( p > 0 \) for the sequence \( k^* \Rightarrow RV \Rightarrow \Gamma \). In this case there is \( l \)-torsion for \( l \neq p \), but no \( p \)-torsion, and the corresponding group is \( \text{GL}_n(\mathbb{Z}[1/p]) \times C^n \).

Note as a corollary that there can be no definable sections of \( B \rightarrow C \) over an infinite definable subset of \( C \).

**Lemma 3.28.** Let \( 0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0 \) be as in Lemma 3.26. Let \( X \subset B^n \) be definable, and let \( f : X \rightarrow B^l \) be a definable function. \( X \) may be partitioned into finitely many pieces \( X' \), such that on each \( X' \)

(1) \( f(x) = Mx + b(x) \), where \( M \) is a \( l \times n \)-integer matrix and \( \vartheta b(x) \) is constant.

(2) There exists \( g \in \text{GL}_n(\mathbb{Z}) \) such that \( \vartheta g \) factors through a projection \( B^n \rightarrow_{\theta} B^k \), where \( \vartheta\pi(X') \) is one point of \( C^k \).

**Proof.** We first prove (1,2) for complete types.

(1) This reduces to \( l = 1 \). Let \( P \) be a complete type of elements of \( X \). Then on \( P \) we have \( \vartheta \circ f(x) = \sum m_i \vartheta(x)_i + d \) for some constant \( d \). (Lemma 3.26).

Thus \( f(x) = \sum m_i x_i + b(x) \), where \( b(x) = f(x) - \sum m_i x_i \), and \( \vartheta b(x) = d \) is constant.

(2) Let \( \pi : B^n \rightarrow B^k \) be a projection such that \( \vartheta\pi(X) \) is one point of \( C^k \), and with \( k \) maximal. So \( P \subset P' \times P'' \), \( P' \subset B^{n-k} \), \( P'' \subset B^k \), and \( \vartheta(P'') \) is a single point of \( C^k \), while \( \vartheta(P') \) is not contained in any proper hypersurface \( \sum n_i x_i = \text{constant} \). Pick \( b'' \in P'' \).

Let \( \gamma = (\gamma_1,\ldots,\gamma_k) \in \vartheta(P') \), with \( \gamma_i \) not in any such hypersurface. Let \( a = (a_1,\ldots,a_k) \), \( \vartheta(a_i) = \gamma_i \), and let \( a' \) be another point with \( \vartheta(a') = \gamma \). Let \( e = f(a,b) \). Then \( \vartheta(a'/b,e) = \vartheta(a'/b,e) \), so \( f(a,b) \) depends only on \( b \in P'' \) and not on \( a \) (with \( (a,b) \in P \)).
Since (1), (2) hold on each complete type, there exists a definable partition such that they hold on each piece. \qed

3.4. V-minimality. We assume from now on that T is a theory of C-minimal valued fields, of residue characteristic 0. When using the many-sorted language, we will still say that T is a theory of valued fields when T = Th(F, RV(F)) for some valued field F, possibly with additional structure. A C-minimal T satisfying assumption (3) below will be said to have centered closed balls. If in addition (1), (2) hold, we will say T is V-minimal. Expansions by definition of the language, i.e. the addition of a relation symbol R(x) to the language along with a definition (\forall x)(R(x) \iff \phi(x)) to the theory, do not change any of our assumptions. Thus we can assume that T eliminates quantifiers.

(1) **Induced structure on RV** T contains ACVF(0, 0), and every parametrically T-definable relation on RV* is parametrically definable in ACVF(0, 0).

(2) **Definable completeness** Let A \subseteq M \models T, and let W \subset \mathcal{B} be a T_A-definable family of closed balls linearly ordered by inclusion. Then \cap W \neq \emptyset.

(3) **Choosing points in closed balls** Let M \models T, A \subseteq VF(M), and let b be an almost A-definable closed ball. Then b contains an almost A-definable point.

T will be called effective if every definable finite disjoint union of balls contains a definable set, with exactly one point in each. A substructure A of a model of T will be called effective if T_A is effective.

If every definable finite disjoint union of rv-balls contains a definable set, with exactly one point in each, we can call T rv-effective. However:

**Lemma 3.29.** Let T be V-minimal. Then T is effective iff it is rv-effective.

**Proof.** Assume T is rv-effective. Let b be an algebraic ball. If b is closed, it has an algebraic point by Assumption 3.4 3. If b is open, let \widehat{b} be the closed ball surrounding it. Then \widehat{b} has an algebraic point a. Let f(x) = x - a. Then f(b) is an rv-ball, so by rv-effectivity it has an algebraic point a'. Hence a' + a is an algebraic point of b. \qed

In general, effectivity is needed for lifting morphisms from RV to VF, not for the “integration” direction.

If T is V-minimal and A is a VF \cup RV \cup \Gamma - generated structure, we will see that T_A is V-minimal too. The analog for points in open balls is true but only for VF \cup \Gamma-generated substructures; for thin annuli it is true only for VF-generated structures. For this reason the condition on closed balls is more flexible; luckily we will be able to avoid the others.

**Lemma 3.30.** Let T be a C-minimal theory of valued fields.

Then (1) \iff (2) \iff (3) \iff (4)

(1) T admits quantifier-elimination in a three-sorted language (VF, k, \Gamma), such that for any basic function symbol F with range VF, the domain is a power of VF; and no relations on k, \Gamma beyond the field structure on k and the ordered Abelian group structure on \Gamma.

(2) Every parametrically definable relation on k is parametrically definable in ACF(0); and every parametrically definable relation on \Gamma is parametrically definable in DOAG.

(3) Assumption 3.4 (1).

(4) k, \Gamma and RV are stably embedded.

**Proof.** (1) \Rightarrow (2) : Let \phi(a, x) be an atomic formula with parameters a = (a_1, \ldots, a_n) from VF and x = (x_1, \ldots, x_m) variables for the k, \Gamma sorts. Then \phi must have the form \psi(t(a), x), where t is a term (composition of function symbols) VF* \rightarrow (k \cup \Gamma). So \phi(a, x) defines the same
set as $\psi(b,x)$ where $b = t(a)$. Since every formula is a Boolean combination of atomic ones, (2)
follows.

(2) $\implies$ (3) : This follows from Corollary 3.22. The assumptions of Lemma 3.26 are satisfied:
(1) is automatic since by C-minimality $k$ is strongly minimal and $\Gamma$ is $O$-minimal; (2)
follows from C-minimality; (3),(4) follow from the assumptions on $k, \Gamma$.

(3) immediately implies (4).

\[ \square \]

**Lemma 3.31.** Let $T$ be a theory of valued fields satisfying Assumption 3.4 (1), such that res induces a surjective map on algebraic points. Then (1) $\implies$ (2) $\implies$ (3) $\implies$ (4):

1. for any VF-generated substructure $A$ of a model $M$ of $T$, if $\Gamma(A) \neq (0)$, then $acl(A) \models T$.
2. for any VF-generated substructure $A$ of a model of $T$, any $T_A$-definable nonempty finite union of balls contains a nonempty $T_A$-definable finite set.
3. Assumption 3.4 (3) holds.
4. Let $A$ be VF-generated, and $Y$ a finite $A$-definable set of disjoint closed balls. Then there exists an $A$-definable finite set $Z$ such that $|b \cap Z| = 1$ for each $b \in Y$.

**Proof.** We first show:

**Claim** For any VF-generated $A$ with $\Gamma(A) = (0)$, res : $VF(acl(A)) \to k(acl(A))$ is surjective.

**Proof.** It suffices to prove the claim for finitely generated $A$. For $A = \emptyset$ this is true by assumption.

Using induction on the number of generators, it suffices to show that if the Claim holds for $A_0$ and $c \in VF$ then it holds for $A = A_0(c)$.

Since $\Gamma(A) = (0)$, res is defined and injective on VF($A$). If $c \in acl(A_0)$ there is nothing to prove. Otherwise, by injectivity, $res(c) \notin acl(A_0)$. As a consequence of Assumption 3.4 (1), both dcl and acl agree with the corresponding field-theoretic notions on RV, and in particular on the residue field.

By Lemma 3.20,

$$k(A_0(c)) \subseteq dcl(RV(A_0),rv(c)) = dcl(k(A_0), res(c)) = k(A_0)(res(c))$$

Now if $d \in k(acl(A))$ then $d \in k$ and $d \in acl(A)$, so by stable embeddedness of $k$ we have $d \in acl(k(A))$; but $acl(k(A)) = k(A)^{alg}$ by Assumptions 3.4 and 1; so $d \in k(A_0)(res(c))^{alg} \subseteq res(A_0(c))^{alg}$.

Assume (1). If $\Gamma(acl(A)) \neq (0)$ then by (1) $acl(A) \models T$, and in particular every $acl(A)$-definable ball has a point in $acl(A)$, so (2) holds. Assume therefore that $\Gamma(acl(A)) = 0$. Let $b$ be an $acl(A)$-definable ball. Then $b$ must have valuative radius 0. If some element of $b$ has valuation $\gamma < 0$ then all do, and $\gamma \in A$, a contradiction. So $b$ is the (open or closed) ball of radius 0 around some $c \in 0$. If $b$ is closed, then $b = \emptyset$ and $0 \in b$. If $b$ is open, then $b = res^{-1}(b')$ for some element $b'$ of the residue field $k$; in this case $b$ has an $acl(A)$-definable point by the Claim.

(3) is included in (2), being the case of closed balls.

Assume (3). In expansions of ACVF($0,0$), the average of a finite subset of a ball remains within the ball. Thus if $Y$ is a finite $A$-definable set of disjoint balls, by (3), there exists a finite $A$-definable set $Z_0$ including a representative of each ball in $Y$. Let $Z = \{av(b \cap Z_0) : b \in Y\}$, where $av(u)$ denotes the average of a finite set $u$.

\[ \square \]
Lemma 3.32. When $T$ is a complete theory, definable completeness is true as soon as $T$ has a single spherically complete model $M$ in the sense of Ribenboim and Kaplansky: every intersection of nested closed balls is nonempty.

Proof. Clear. □

Let $ACVF^{an}$ denote any of the rigid analytic theories of [23]. For definiteness, let us assume the power series have coefficients in $\mathbb{C}(X)$. See [14] for variants living over $\mathbb{Z}_p$.

Lemma 3.33. $ACVF(0,0)$ is $V$-minimal and effective. So is $ACVF^{an}$.

Proof. $C$-minimality is proved in [24]. Lemma 3.30(1) for ACVF is a version of Robinson’s quantifier elimination; cf. [16].

$ACVF^{an}$ admits quantifier elimination in the sorts $(VF, \Gamma)$ by [23] Theorem 3.8.2. The residue field sort is not explicit in this language, but one can argue as follows. Let $k$ be a large algebraically closed field containing $\mathbb{C}$, and let $K = \bigcup_{n \geq 1} k((X^{1/n}))$ be the Puiseux series ring. Then $K$ admits a natural expansion to a model of the theory. $K$ is not saturated, but by $C$-minimality the induced structure on the residue field is strongly minimal, so $k$ is saturated. Now any automorphism of $k$ as a field extends to an automorphism of $K$ as a rigid analytic structure. Thus every $K$-definable relation on $k$ is algebraic. (This could be repeated over a larger value group if necessary.) Lemma 3.30 (2) thus holds in both cases, hence Assumption 3.4 (1).

Condition Lemma 3.31 (1) is obviously true for ACVF. For $ACVF^{an}$ it is proved in [24].

It is also evident that these theories have a spherically complete model. Thus by Lemma 3.31 and Lemma 3.32, Assumption 3.4 (3) and (2) hold too.

□

Remarks

(1) Lemma 3.31 (1,2,3) remain true for ACVF in positive residue characteristic, but (4) fails.

(2) $ACVF(0,0)$ also admits quantifier-elimination in the two sorted language with sorts $VF, RV$; so Assumption 3.4 (1) can also be proved directly, without going through $k, \Gamma$ as in Lemma 3.30.

(3) (1) is needed for lifting definable bijections of RV to VF, Proposition 6.1, Lemma 6.3. Specifically it implies the truth of assumptions (2) of Lemma 3.21 and (4) of Lemma 3.26. These lemmas are only needed for the injectivity of the Euler characteristic and integration maps, not for their construction and main properties. It is also needed for the theory of differentiation and for comparing derivations in VF and RV; indeed even for posing the question, since in general there is no notion of differentiation on RV. The theory of differentiation itself is needed neither for the Euler characteristic nor for integration of definable sets with a $\Gamma$-volume form. They are required only for the finer theory introduced here of integration of RV-volume forms.

(4) We know no examples of $C$-minimal fields where (2) fails.

(5) Beyond effectivity of $\text{dcl}(\emptyset)$, (3), imposes a condition on liftable of definable functions from VF to $\mathbb{B}^{\mathfrak{a}}$. Let $T_1$ be the theory, intermediate between $ACVF(0,0)$ and a Lipschitz rigid analytic expansion, generated over $ACVF(0,0)$ by the relation

$$\text{val}(f(t_0 x) - y) \geq \text{val}(t_1).$$
on $\mathbb{O}^2$ where $t_0, t_1$ are constants with $\text{val}(t_1) >> \text{val}(t_0) > 0$ and $f$ is an analytic function. It appears that balls do not necessarily remain pointed upon adding VF-points to $T_1$; so (3) is not redundant.

3.5. Definable completeness and functions on the value group. We assume $\mathcal{T}$ is $C$-minimal and definably complete. We show that the property of having centered closed balls is preserved under passage to $T_A$ if $A$ is RV, $\Gamma$, VF-generated; similarly for open balls if $A$ is $\Gamma$, VF-generated. Also included is a lemma stating that every image of an RV-set in VF must be finite; from the point of view of content this belongs to the description of the "basic geography", but we need the lemmas on functions from $\Gamma$ first.

**Proposition 3.34.** Let $M \models \mathcal{T}$, $\gamma = (\gamma_1, \ldots, \gamma_m)$ a tuple of elements of $\Gamma(M)$. Any almost $A(\gamma)$-definable ball $b$ contains an almost $A$-definable ball $b'$.

**Proof.** See [16] Prop. 2.4.4. While the Proposition is stated for ACVF there, the proof uses only $C$-minimality and definable completeness. We review the proof in the case that $b \in A(\gamma)$, i.e. $b = f(\gamma)$ for some definable function $f$ with domain $D \subseteq \Gamma^m$.

Let $P = tp(\gamma/A)$. Let $r(\gamma)$ be the valuative radius of $f(\gamma)$. By $O$-minimality, $r$ is piecewise monotone; since $P$ is a complete type, $r$ is monotone, say decreasing. For $a \in P$ let $P_a = \{b \in P : b < a\}$, and for $b \in P_a$ let $f_a(b)$ be the open ball of size $r(a)$ containing $f(b)$. By Lemma 3.15, the valuative radius map is finite-to-one on $f_a(P_a)$; but by definition it is constant, so $f_a(P_a)$ is finite. Using the linear ordering, $f_a(P_a)$ is constant on each complete type over $a$. Pick $b_1 \in P, \epsilon \in \Gamma$ with $\epsilon > 0$ but very small (over $A(b_1), \gamma$), and $\epsilon' \in \Gamma$ with $\epsilon' > 0$ but $\epsilon'$ very small (over $A(b_1, \epsilon))$. Let $b_2 = b_1 + \epsilon, a = b_2 + \epsilon'$. Then $tp(b_1, a/A) = tp(b_2, a/A)$, so $f_a(b_1) = f_a(b_2)$. Now if $f(b_1), f(b_2)$ are disjoint, let $\delta = \text{val}(x_1 - x_2)$ for (some or any) $x_i \in f(b_i)$. Then $r(b_2) > \delta$. Since $\epsilon'$ is very small, $r(a) > \delta$ also. So $f_a(b_1), f_a(b_2)$ are distinct, a contradiction. Thus $f(b_1) \subset f(b_2)$. Since $tp(a/A) = tp(b_2/A)$, we have $f(y) \subset f(a)$ for some $y \in P_a$. If $f(y) \subset f(a)$ for all $y \in P_a$, we are done; otherwise let $c(a)$ be the unique smallest element such that $f$ is monotone on $(c(a), a)$. We saw however that $f$ is monotone on $(d, c(a))$ for some $d < c(a)$, hence also on $(d, a)$, a contradiction. So $f$ is monotone with respect to inclusion. By compactness, this is true on some $A$-definable interval hence on some interval $I$ containing $P$.

Let $U \cap_{a \in I} f(a)$. By definable completeness (2) $U \neq \emptyset$. Clearly $U$ is a ball, and $U \subseteq b$. □

**Lemma 3.35.** Let $M \models \mathcal{T}$, $\gamma = (\gamma_1, \ldots, \gamma_m)$ a tuple of elements of $\Gamma(M)$. Then any $A(\gamma)$-definable ball contains an $A$-definable ball. If $Y$ is a finite $A(\gamma)$-definable set of disjoint balls, then there exists a finite $A$-definable set $Y'$ of balls, such that each ball of $Y$ contains a unique ball of $Y'$.

**Proof.** This reduces immediately to $m = 1$. For $m = 1$, by Proposition 3.34, any almost $A(\gamma)$-definable ball $b$ contains an almost $A$-definable ball $b'$. Thus given a finite $A(\gamma)$-definable set $Y$ of disjoint balls, there exists a finite $A$-definable set $Z$ of balls, such that any ball of $Y$ contains a ball of $Z$. Given $b \in Y$, let $b'$ be the smallest ball containing every sub-ball $c$ of $b$ with $c \in Z$. Then $Y' = \{b' : b \in Y\}$ is $A(\gamma)$-definable, finite, almost $A$-definable, and (since $b'$ is disjoint from $b_2$ if $b_1 \neq b_2 \in Y)$ each ball of $Y$ contains a unique ball of $Y'$. Using elimination of imaginaries in $\Gamma$, by Example 2.2, being $A(\gamma)$-definable and almost $A$-definable, $Y'$ is $A$-definable. □

The following corollary of Lemma 3.35 concerning definable functions from $\Gamma$ will be important for the theory of integration with an additive character in §11.
Corollary 3.36. Let $Y$ be a definable set admitting a finite-to-one map into $\Gamma^n$, and let into $h$ be a definable map on $Y$ into $VF$ or $VF/\emptyset$ or $VF/M$. Then $h$ has finite image.

Proof. One can view $h$ as a function from a subset of $\Gamma^n$ into finite sets of balls. Since a ball whose radius is definable containing a definable ball is itself definable, Lemma 3.35 implies that $h(\gamma) \in \text{ad}(\emptyset)$ for any $\gamma \in \Gamma^n$. By Lemma 2.6, the corollary follows. \qed

Corollary 3.37. Let $Y \subseteq (RV \cup \Gamma)^n$ and $Z \subseteq VF \times Y$ be definable sets, with $Z$ invariant for the action of $M$ on VF. Then for all but finitely many $\emptyset$-cosets $C$, $Z \cap (C \times Y)$ is a rectangle $C \times Y'$.

Proof. Let $p : (RV \cup \Gamma)^n \to \Gamma^n$ be the natural projection, and for $\gamma \in \Gamma^n$ let $Z_\gamma$ be the fiber. For each $\gamma$, by Lemma 3.16, there exists a finite $F(\gamma) \subseteq VF/\emptyset$ such that for any $\emptyset$-coset $C \notin F(\gamma)$, $Z_\gamma \cap (C \times Y)$ is $\emptyset$-invariant. Now $\{(u, \gamma) : u \in F(\gamma)\}$ projects finite-to-one to $\Gamma^n$, so by Lemma 3.36, this set projects to a finite subset of $VF/\emptyset$. Thus there exists a finite $E \subseteq VF/\emptyset$ such that for any $\gamma$, and any $\emptyset$-coset $C \notin E$, $Z_\gamma \cap (C \times Y)$ is $\emptyset$-invariant. In other words, for any $C \notin E$, $Z \cap (C \times Y)$ is $\emptyset$-invariant. \qed

Lemma 3.38. Let $M \models T$, $A$ a substructure of $M$ (all imaginary elements allowed), and let $r = (r_1, \ldots, r_m)$ be a tuple of elements of $RV(M) \cup \Gamma(M)$. Then any closed ball almost defined over $A(r)$ contains a ball almost defined over $A$.

Proof. This reduces to $m = 1$, $r = r_1$; moreover using Lemma 3.35, to the case $r \in RV(M), \text{val}_y(r) = \gamma \in A$. Let $E = \{y \in RV : \text{val}_y(y) = \gamma\}$. Then $E$ is a $k^*$-torso, and so is strongly minimal within $M$. If $c$ is almost defined over $A(r)$, there exists an $A$-definable set $W \subseteq A \times B_{\mathcal{D}}$, with $W(c) = \{y : (c, y) \in E\}$. But then $W$ is a finite union of strongly minimalities, hence so is the projection $P$ of $W$ to $B_{\mathcal{D}}$. But any strongly minimal subset of $B_{\mathcal{D}}$ is finite (otherwise it admits a definable map onto a segment in $\Gamma$; but $\Gamma$ is linearly ordered and cannot have a strongly minimal segment.) So $c \in P$ is almost defined over $A$. \qed

Lemma 3.39. Let $M \models T$, $T$ $C$-minimal with centered closed balls. Let $B$ be a substructure of $VF(M) \cup RV(M) \cup \Gamma(M)$. Then every $B$-definable closed ball has a $B$-definable point. If $Y$ is a finite $B$-definable set of disjoint closed balls, there exists a finite $B$-definable set $Z \subseteq M$, meeting each ball of $Y$ in a unique point.

Proof. We may take $B$ to contain a subfield $K$ and be generated over $K$ by finitely many points $r_1, \ldots, r_k \in RV$. Let $Y$ be a a finite $B$-definable set of disjoint closed balls, and let $b \subseteq Y$. We may assume all elements of $Y$ have the same type over $B$. By Lemma 3.38, there exists a closed ball $b'$ defined almost over $K$ and contained in $b$. By Assumption 3.4 there exists a finite $K$-definable set $Z'$ meeting $b'$ in a unique point. Let $Y' = \{b'' : b'' \cap Z' \neq \emptyset\}$, and $Z = \{v : Z \cap V' \neq \emptyset\}$. Then $Z$ meets each ball of $Y'$ in a unique point, and $Z, Y'$ are $B$-definable. As for $Y \setminus Y'$, it may be treated inductively. \qed

Corollary 3.40. Let $M \models T$, $T$ $C$-minimal with centered closed balls, and effective. Let $B$ be an almost $\Gamma$-generated substructure. Then $T$ is effective.

Proof. Same as the proof of Lemma 3.39, using Lemma 3.34 in place of Lemma 3.38. \qed

Lemma 3.41. Let $Y$ be a $T$ - definable set admitting a finite-to-one map into $RV^n$. Let $g : Y \to VF^m$ be another definable map. Then $g(Y)$ is finite.
Proof. It suffices to prove this for $T_A$, where $A \models T$. We may also assume $m = 1$. We will use the equivalence (3) $\iff$ (4) of Lemma 2.6. If $g(Y)$ is infinite, then by compactness there exists $a \in g(Y)$ $a \not\in acl(A)$. But for some $b$ we have $a = g(b)$, so if $c = f(b)$, we have $c \in RV^n$, $a \in acl(c)$. Thus it suffices to show:

(*) If $a \in VF$, $c \in RV^n$ and $a \in acl(A(c))$, then $a \in acl(A)$.

This clearly reduces to the case $n = 1$, $c \in RV$. Let $d = \text{val}_{TV}(c)$, $A' = acl(A(d))$. Then $c$ lies in an $A'$-definable strongly minimal set $S$ (namely $S = \text{val}_{TV}^{-1}(d)$). Using Lemma 2.6 in the opposite direction, since $a \in acl(A'(c))$ there exists a finite-to-one map $f : S' \to S$ and a definable map $g' : S' \to VF$ with $a \in g'(f^{-1}(S'))$. By Corollary 3.13, $g'(f^{-1}(S'))$ is finite. Hence $a \in acl(A(d))$. But then by Lemma 3.36, $a \in acl(A)$.

In particular, there can be no definable isomorphism between an infinite subset of $RV^n$ and one of $VF^n$.

Lemma 3.42. Let $M \models T$, $T$ $C$-minimal with centered closed balls, and let $A$ be a substructure of $M$. Write $A_{VF}$ for the field elements of $A$, $A_{RV}$ for the RV-elements of $A$.

Let $c \in RV(M)$, and let $A'(c) = acl(A \cup \{ c \})$. Then $A(c)_{VF} \subset (A_{VF})^{a^g}$, and $rv(A(c)_{VF}) \cap A_{RV} = rv(A_{VF})$.

Proof. Let $e \in A(c)_{VF}$. Then $e = f(c)$ for some $A$-definable function $f : W \to VF$, $W \subseteq RV$. By Lemma 3.41, the image of $f$ is finite, $e \in acl(A)$. This proves the first point. Now if $d \in RV_A$ and $rv^{-1}(d)$ has a point in $A(c)$, then it has a point in $(A_{VF})^{a^g}$, by Assumption 3.4 (3)

3.6. Transitive sets in dimension one. Let $b$ be a closed ball in a valued field. Then the set $\text{Aff}(b)$ of maximal open sub-balls of $b$ has the structure of an affine space over the residue field. We will now begin using this structure. Without it, more general transitive annuli (missing more than one ball) could exist.

Lemma 3.43. Let $X \subseteq VF$ be a transitive $T_B$-definable set, where $B$ is some set of imaginaries. Then $X$ is a finite union of open balls of equal size, or a finite union of closed balls of equal size, or a finite union of thin annuli.

Proof. By $C$-minimality, $X$ is a finite Boolean combination of balls. There are finitely many distinct balls $b_1, \ldots, b_n$ that are almost contained in $X$ (i.e. $b_i \setminus X$ is contained in a finite union of proper sub-balls of $b_i$) but such that no ball larger than $b_i$ is almost contained in $X$. These $b_i$ must be disjoint. If some of the $b_i$ have different type than the others, their union (intersected with $X$) will be a proper $B$-definable subset of $X$. Thus they all have the same type over $B$; in particular they have the same radius $\beta$.

Consider first the case where the balls $b_i$ are open, then $b_i \subseteq X$: otherwise $b_i \setminus X$ is contained in a unique smallest ball $c_i$; say $c_i$ has radius $\alpha$; then $\alpha > \beta$. Let $b'_i$ be the open ball of radius $(1/2)(\alpha + \beta)$ around $c_i$; then $\cup_i b'_i$ is a $B$-definable proper subset of $X$, a contradiction. Thus in the case of open balls, $X \supseteq \cup_i b_i$ and therefore $X = \cup_i b_i$.

If the balls $b_i$ are closed, let $c_{ij}$ be a minimal finite set of sub-balls of $b_i$ needed to cover $b_i \setminus X$. The same argument shows that no $c_{ij}$ has radius $< \beta$. Thus all $c_{ij}$ are elements of the set $V_i$ of open sub-balls of $b_i$ of radius $\beta$. Now $V_i$ is a $k$-afne space, and if there is more than one $c_{ij}$ then over $acl(B)$, $V_i$ admits a bijection with $k$; so there is a finite $B$-definable set of bijections $V_i \to k$; since any finite definable subset of $k$ is contained in a strictly bigger one, the union of the pullbacks gives a $B$-definable subset of $V_i$ properly containing the $c_{ij}$, leading to a proper $B$-definable subset of $X$. Thus either $b_i \subseteq X$ (and then $X = \cup_i b_i$), or else $b_i \setminus c_i \subseteq X$...
for a unique maximal open sub-ball \( c_i \). Now \( \bigcup c_i \) intersects \( X \) in a proper subset, which must be empty. So in this case, \( X = \bigcup \{ b_i \setminus c_i \} \).

Let \( X \) be a transitive \( B \)-definable set. Call \( Y \subseteq X \) potentially transitive if there exists \( B' \supset B \) such that \( Y \) is \( B' \)-definable and \( B' \)-transitive. Let \( \mathcal{F}(X) \) be the collection of all proper potentially transitive subsets \( Y \) of \( X \). Let \( \mathcal{F}_{\text{max}}(X) \) be the set of maximal elements of \( \mathcal{F}(X) \).

**Lemma 3.44.**

1. If \( X \) is an open ball, \( \mathcal{F}_{\text{max}}(X) = \emptyset \)
2. If \( X \) is a closed ball, \( \mathcal{F}_{\text{max}}(X) = \{ X \setminus \{ Y : Y \in \text{Aff}(X) \} \}
3. If \( X \) is a thin annulus \( X' \setminus Y \) with \( X' \) closed, then \( \mathcal{F}_{\text{max}}(X) = \text{Aff}(X) \setminus \{ Y \} \)

**Proof.** Any element of \( \mathcal{F}(X) \) must be a ball or a thin annulus, so the lemma follows by inspection.

**Lemma 3.45.** Let \( b \) be a transitive closed ball (respectively thin annulus). Let \( Y = \text{Aff}(b) \) be the set of maximal open sub-balls of \( b \). Then the group of automorphisms of \( Y \) over \( k \) is definable, acts transitively on \( Y \), and in fact contains \( G_a(k) \) (respectively \( G_m(k) \)).

If \( b, b' \) are transitive definable closed balls, and \( F : b \to b' \) a definable bijection, let \( F_* : Y(b) \to Y(b') \) be the induced map. Then \( F_* \) is a homomorphism of affine spaces, i.e. there exists a vector space isomorphism \( F_{**} : V(b) \to V(b') \) between the corresponding vector spaces, and \( F_{**}(a + v) = F_{**}(a) + F_{**}(v) \). If \( b = b' \) then \( F_{**} = \text{Id} \).

**Proof.** \( Y = \text{Aff}(b) \) is transitive, and there is a \( k \)-affine space structure on \( Y \) (respectively a \( k \)-vector space structure on \( V = Y' \cup \{ 0 \} \)). Let \( G = \text{Aut}(Y/k) \) be the subgroup of the group \( \text{Aff} = (G_m \ltimes G_a)(k) \) of affine transformations of \( Y \) that preserve all definable relations. By definition, this is an intersection of definable subgroups of \( \text{Aff} \). However there is no infinite descending chain of definable subgroups of \( \text{Aff} \), so \( G \) is definable.

If \( G \) is finite, then \( Y \subseteq \text{acl}(k) \), and it follows (cf. §2.1.5 that there are infinitely many algebraic points of \( Y \), contradicting transitivity. Thus \( G \) is an infinite subgroup of \( (G_m \ltimes G_a)(k) \) such that the set of fixed points \( Y^G \) is empty. So \( G \) must contain a translation, and by strong minimality it must contain \( G_a(k) \). Similarly in the case of the annulus \( G \) is an infinite definable subgroup of \( G_m(k) \), so it must equal \( G_m(k) \).

As for the second statement, \( F \) induces a group isomorphism \( \text{Aut}(Y(b)/k) \to \text{Aut}(Y(b')/k) \), and hence an isomorphism \( G_a(k) \to G_a(k) \), which must be multiplication by some \( \gamma \in k^* \). Since \( G_a(k) \) acts by automorphisms on \( (Y(b), Y(b')) \), any definable function \( Y(b) \to Y(b') \) commutes with this action and hence has the specified form. If \( b = b' \) then \( Y(b) = Y(b') \); now if \( F_{**} \neq \text{Id} \) then \( F_* \) would have a fixed point, contradicting transitivity.

**Lemma 3.46.** Let \( b \) be a transitive \( T_B \)-definable closed (open) ball. Let \( F \) be a \( B \)-definable function, injective on \( b \). Then \( F(b) \) is a closed (open) ball.

**Proof.** By Lemma 3.43, since \( F(b) \) is also transitive, it is either a closed ball, or an open ball, or a thin annulus. We must rule out the possibility of a bijection between such sets of distinct types.

Consider the collection \( \mathcal{F}_{\text{max}}(b) \) defined above. Any definable bijection between \( b \) and \( b' \) clearly induces a bijection \( \mathcal{F}_{\text{max}}(b) \to \mathcal{F}_{\text{max}}(b') \). By Lemma 3.44, the bijective image of an open ball is an open ball.

Let \( b \) be a closed ball, \( b' = b'' \setminus b''' \) a closed ball minus an open ball, \( A = \mathcal{F}_{\text{max}}(b) \simeq \text{Aff}(b) \) \( A' = \mathcal{F}(b') \simeq \text{Aff}(b'' \setminus b''') \), \( G = \text{Aut}(A/k) \), \( G' = \text{Aut}(A'/k) \). Then a definable bijection \( A \to A' \) would give a definable group isomorphism \( G \to G' \). But by Lemma 3.45, \( G' = G_m(k) \) while \( G \) contains \( G_a(k) \), so no such isomorphism is possible (say because \( G_m(k) \) has torsion points.)
Thus the three types are distinct. □

We will see later that there can be no definable bijection between an open and a closed ball, whether transitive or not.

**Lemma 3.47.** Let $b$ be a transitive ball. Then every definable function on $b$ into $RV \cup \Gamma$ is constant. If $b$ is a transitive thin annulus, every definable function on $b$ into $k \cup \Gamma$ is constant. More generally, this is true for definable functions into definable cosets $C$ of $k^*$ in $RV$ that contain algebraic points.

**Proof.** When a ball $b$ is transitive, it is actually finitely primitive. For if $E$ is a $B$-definable equivalence relation with finitely many classes, then exactly one of these classes is generic (i.e. is not contained in a finite union of proper sub-balls of $b$.) This class is $B$-definable, hence must equal $b$.

Thus a definable function on $b$ with finite image is constant.

Let $F$ be a definable function on $b$ into $\Gamma$. If $F$ is not constant, then for some $\gamma \in \Gamma$, $F^{-1}(\gamma)$ is a proper subset of $b$; it follows that some finite union of proper sub-balls of $b$ is $\gamma$-definable. By Lemma 3.35, it follows that some such finite union is already definable, a contradiction.

Thus it suffices to show that functions into a single coset $C = \val^{-1}(\gamma)$ of $k^*$ are constant on $b$.

Assume first that $b$ is open, or a properly infinite intersection of balls. By Lemma 3.19 definable functions on $b$ into $C$ are generically constant; but then by transitivity they are constant.

Now suppose $b$ is closed, or a thin annulus. Let $Y$ be the set of maximal open sub-balls $b'$ of $b$. Each $b' \in Y$ is transitive over $T_{b'}$, so $F|b'$ is constant. Thus $F$ factors through $Y$.

In the case of the annulus, by Lemma 3.45, $G_m(k)$ acts transitively on $Y$ by automorphisms over $k$. This suffices to rule out nonconstant functions into $k$. More generally, if a coset $C$ of $k^*$ has algebraic points, then $Aut(C/k)$ is finite. Since $Aut(Y/k)$ is transitive, it follows that if $f : Y \rightarrow C$ is definable then $f(Y)$ is finite. But $Y$ is finitely primitive, so $f(Y)$ is a point.

Assume finally that $b$ is a closed ball. Using Lemma 3.45, we can view $G_a(k)$ as a subgroup of $Aut(Y/k)$. $Aut(C/k)$ is contained in $G_m(k)$. Let $S = Aut(Y \times C/k) \cap (G_a(k) \times G_m(k))$. Then $S$ projects onto $G_a(k)$. By strong minimality, $S \cap (G_a(k) \times 0)$ is either $G_a(k)$ or a finite group. In the first case, $S = G_a \times T$ for some $T \leq G_m$. In the latter, $S$ is the graph of an finite-to-one homomorphism $G_a \rightarrow T$; but this is impossible. Thus $G_a \times 0 \leq S$ and $G_a$ acts transitively on $Y$ by automorphisms fixing $C$; it follows that $F$ is constant. □

### 3.7. Resolution and finite generation.

**Lemma 3.48.** Let $A \leq B$ be substructures of a model of $T$. Assume $B$ is finitely generated over $A$. Then $RV(B)$ is finitely generated over $RV(A)$. Also, if $RV(A) \leq C \leq RV(B)$ then $C$ is finitely generated over $RV(A)$.

**Proof.** Suppose $\Gamma(B)$ has infinitely many elements, $\mathbb{Q}$-linearly independent modulo $\Gamma(A)$. By Lemma 3.1, they are algebraically independent. By Lemma 3.20, they lift to algebraically independent elements of $B$ over $A$, contradicting the assumption of finite generation. Thus $rk_0(\Gamma(B)/\Gamma(A)) < \infty$. It is thus clear that any substructure of $\Gamma(B)$ containing $\Gamma(A)$ is finitely generated over $\Gamma(A)$. So it suffices to show that $RV(B)$ is finitely generated over $A \cup \Gamma(B)$; replacing $A$ by $A \cup \Gamma(B)$, we may assume $\Gamma(B) = \Gamma(A)$. In this case $RV(B) \subset RES$. See [17] Proposition 7.3 for a proof stated for $ACVF_A$, but valid in the present generality. Here is a sketch. One looks at $B = A(c)$ with $c \in VF$. If $c \in acl(A)$ then the Galois group $Aut(acl(A)/A(c))$ has finite index in $Aut(acl(A)/A)$. Hence the same is true of their images in $Aut(acl(A) \cap RV)$, and since $RV$ is stably embedded (by clause (1) of the definition of
V-minimality) it follows that there exists a finite subset $C'$ of $A(c) \cap RV$ such that any automorphism of $acl(A)$ fixing $A(C')$ fixes $A(c) \cap RV$. By Galois theory for saturated structures (§2.1.3) $C'$ generates $A(c) \cap RV$ over $A$.

On the other hand if $c \notin acl(A)$, then $tp(c/acl(A))$ agrees with the generic type over $A$ of either a closed ball, an open ball, or an infinite intersection of balls. In the latter two cases, $\text{RES}(A) = \text{RES}(B)$ using Lemma 3.19. In the case of a closed ball $b$, let $b'$ be the unique maximal open sub-ball of $b$ containing $c$. Then $b' \in A(c)$, and $tp(c/A(b'))$ is generic in the open ball $b'$. Thus by Lemma 3.17, $\text{RES}(B) = \text{RES}(A(b'))$ so it is 1-generated. \[ \Box \]

Recall $\mathfrak{B} = \mathfrak{B}^o \cup \mathfrak{B}^{cl}$ is the sort of closed and open balls.

We require a variant of a result from [17] on canonical resolutions. We state it for $\mathfrak{B}$-generated structures, but it can be generalized to arbitrary ACVF-imaginaries ([16]).

The proposition and corollaries will have the effect of allowing free use of the technology constructed in this paper over arbitrary base. (cf. Proposition 8.3.)

For this proposition, we allow $\mathfrak{B}$ (and $\Gamma$) as sorts, in addition to VF and RV; so that a structure is a subset of $\mathfrak{B}, \Gamma$ of a model of $\mathbf{T}$, closed under definable functions.

Assume for simplicity that $\mathbf{T}$ has quantifier elimination. (cf. 3.4)

Let us call a structure $A$ resolved if any ball and any thin annulus defined over $acl(A)$ has a point over $acl(A)$.

**Lemma 3.49.** Let $\mathbf{T}$ be $\text{V}$-minimal. Let $M \models \mathbf{T}$, and $A$ be a substructure of $M$. Then (1),(2) are equivalent; if $\Gamma(A) \neq (0)$ then (3) is equivalent to both.

1. $A$ is effective and $\text{VF}(acl(A)) \rightarrow \Gamma(A)$ is surjective.
2. $A$ is resolved.
3. $acl(A)$ is an elementary submodel of $M$.

**Proof.** Clearly (3) implies (1) and (2) implies (1). To prove that (1) implies (3) it suffices to show that every definable $\phi(x)$ of $T_A$ in one variable, with a solution in $M$, has a solution in $A$. If $x$ is an RV-variable it suffices to show that $\phi(rv(y))$ has a solution; so we may assume $x$ is a VF- variable, so $\phi$ defines $D \subseteq VF$. By C-minimality $D$ is a finite Boolean combination of balls. $D$ can be written as a finite union of definable sets of the form $\cup_{j=1}^{m} D_j \setminus E_j$, where for each $j$, $D_j$ is a closed ball, and $E_j$ a finite union of maximal open sub-balls of $D_j$, or $D_j$ is an open ball and $E_j$ a proper sub-ball of $D_j$, or $E_j = \emptyset$, or $D_j = K$. In the third case, by effectiveness there exists a finite set meeting each $D_j$ in a point; since $A = acl(A)$, this finite set is contained in $A$; so $D(A) \neq \emptyset$, as required. In the first and second cases, there exists similarly a finite set $Y$ meeting each $E_j$. Since $A = acl(A)$, $Y \subseteq A$. By picking a point and translating by it, we may assume $0 \in E_j$ for some $j$. Say $E_j$ has valuated radius $\alpha$; picking a point $d \in A$ with $\text{val}(d) = \alpha$ and dividing, we may assume $\alpha = 0$. Now in the open case any element of valuation 0 will be in $D_j$. In the closed case, the image of $E_j$ under $res$ is a finite subset of the residue field; pick some element $\tilde{a}$ of $k(A)$ outside this finite set; by effectivity, pick $a \in A$ with $\text{res}(a) = \tilde{a}$; then $a \in D$. In the fourth case, we use the assumption that $\Gamma(A) \neq (0)$. This proves (3).

It remains to show that (1) implies (2). Let $b$ be a thin annulus defined over $acl(\emptyset)$; so $b = b' \setminus b''$ for a unique closed ball $b'$ and maximal open sub-ball $b''$. By effectivity, $b''$ has an algebraic point, so translation we may assume $0 \in b''$. In this case the assumption that $\text{VF}(acl(A)) \rightarrow \Gamma(A)$ is surjective gives a point of $b' \setminus b''$. \[ \Box \]

If $T_0$ is $\text{V}$-minimal, $A$ is a finitely generated structure (allowing $\mathfrak{B}$, or even $\text{ACVF}$-imaginaries), and $T = (T_0)_A$, we will call $T$ a finitely generated extension of a $\text{V}$-minimal theory.
Remark 3.50. If $A$ is effective, then $A$ is $\text{VF} \cup \Gamma$-generated. If $A$ is resolved, then $A$ is $\text{VF}$-generated.

Proposition 3.51. Let $T$ be $\text{V}$-minimal.

1. There exists an effective structure $E_{\text{eff}}$ admitting an embedding into any effective structure $E$. We have $\text{RV}(E_{\text{eff}}), \Gamma(E_{\text{eff}}) \subseteq \text{dcl}(\emptyset)$.
2. There exists a resolved $E_{\text{rel}}$ embedding into any resolved structure $E$. We have $k(E_{\text{rel}}), \Gamma(E_{\text{rel}}) \subseteq \text{dcl}(\emptyset)$. In fact $C(E_{\text{rel}}) \subseteq \text{dcl}(\emptyset)$ for any coset $C$ of $k^*$ in $\text{RV}$ that contain algebraic points.
3. Let $A$ be a finitely generated substructure of a model of $T$, in the sorts $\text{VF} \cup B$. Then (1), (2) hold for $T_A$.

Proof. (1) Let $(b_i)_{i<\lambda}$ enumerate the definable balls. Define a tower of $\text{VF}$-generated structures $A_i$, and a sequence of balls $b_i$, as follows. Let $A_0 = \text{dcl}(\emptyset)$; if $\kappa$ is a limit ordinal, let $A_\kappa = \bigcup_{i<\kappa} A_i$. Assume $A_\kappa$ has been defined. If possible, let $b_i$ be an $A_i$-definable, $A_i$-transitive ball, not a point; and let $c_i$ be any point of $b_i$. If no such ball $b_i$ exists, the construction ends, and we let $E_{\text{eff}} = A_i$ for this $i$.

Suppose $E$ is any effective substructure of a model of $T$. We can inductively define a tower of embeddings $f_i: A_i \to E$. At limit stages $\kappa$ let $f_\kappa = \bigcup_{i<\kappa} f_i$. Given $f_i$ with $A_i \neq E$, let $b_i$ be the image under $f$ of $b_i$. By effectivity, $b_i$ has a point $c_i \in E$. Since $b_i$ is transitive over $A_i$, the formula $x \in b_i$ generates a complete type; so $tp(c_i/A_i)$ is carried by $f$ to $tp(c_i/A_i')$. Thus there exists an embedding $f_{i+1}: A_{i+1} \to E$ extending $f_i$, and with $c_i \to c_i'$.

Each $A_i$ is $\text{VF}$-generated; by Lemma 3.31 (3) $\Rightarrow$ (4), the process can only stop when $A_i = E_{\text{eff}}$. This shows that $E_{\text{eff}}$ embeds into $E$, and at the same time that the construction of $E_{\text{eff}}$ itself must halt at some stage (of cardinality $\leq |T|_i$).

By construction, $E_{\text{eff}}$ is $\text{VF}$-generated; and hence $T_{E_{\text{eff}}}$ is $\text{V}$-minimal. Moreover there are no $E_{\text{eff}}$-definable $E_{\text{eff}}$-transitive balls (except points). In other words all $E_{\text{eff}}$-definable balls are centered. By $\text{V}$-minimality (3) every closed ball has a definable point, so every centered ball has one. So $E_{\text{eff}}$ is effective.

It remains only to show that $\text{RV}(E_{\text{eff}}), \Gamma(E_{\text{eff}}) \subseteq \text{dcl}(\emptyset)$. We show inductively that $\text{RV}(A_i), \Gamma(A_i) \subseteq \text{dcl}(\emptyset)$. At limit stages this is trivial, and at successor stages it follows from Lemma 3.47.

(2) Identical to (1), but using thin annuli as well as balls. If a thin annulus is not transitive, it contains a proper nonempty finite union of balls, so by $\text{V}$-minimality it contains a proper nonempty finite set. Hence the construction of the $A_i$ stops only when $A_i$ is resolved.

(3) Let $A_0 = (A \cap (\text{VF} \cup \Gamma))$. $A$ is generated over $A_0$ by some $b_1, \ldots, b_n \in B$ with $b_i$ of valutative radius $\gamma_i \in A_0$. Since $T_{A_0}$ is $\text{V}$-minimal, we may assume $T = T_{A_0}$ and $A$ is generated by $b_1, \ldots, b_n$, with $\gamma_i$ definable.

Let $J$ be a subset of $\{1, \ldots, n\}$ of smallest size such that $\text{acl}(\{b_j : j \in J\}) = \text{acl}(\{b_1, \ldots, b_n\})$. By minimality, no $b_j$ is algebraic over $\{b_{j'} : j' \in J, j' \neq j\}$. Let $j \in J$, and let $Y_j$ be the set of balls of radius $\gamma_j$; then $Y_j$ is a definable family of disjoint balls. By Lemma 3.8 for $T' = T_{<\{b_{j', i \in J, j' \neq j}\}}, b_j$ is transitive in $T_{b_j}$, i.e. in $T_{<b_{j', j' \in J}}$; hence $b_j$ is transitive over $\text{acl}(b_1, \ldots, b_n) = \text{acl}(A)$. Let us now show, using induction on $|J|$, that $\Pi_{j \in J} b_j$ is transitive over $A$. Let $c_j \in b_j$. By Lemma 2.10 the $\{b_{j'} : j' \in J, j' \neq j\}$ remain algebraically independent over $< c_j >$. Thus by induction, $\Pi_{j \neq j'} b_{j'}$ is transitive over $A(c_j)$; since $b_j$ is transitive over $A$, $\Pi_{j \neq j'} b_{j'}$ is too. Let $A' = A(c_j : j \in J)$.

Claim If $B$ is a $\text{VF} \cup \Gamma$-generated structure containing $A$, then $A'$ embeds into $B$ over $A$. 
Proof. Since $B$ is $VF \cup \Gamma$-generated, every ball of $T_B$ is centered, in particular $b_j$ has a point $c_j'$ defined over $T_B$. Let $c' = (c_j' : j \in J)$. By transitivity of $\Pi_{j \in J} b_j$ we have $tp(c/A) = tp(c'/A)$. So $A'$ embeds into $B$.

Note that $A'$ is almost $VF \cup \Gamma$-generated; indeed since $\gamma$ is definable, $b_i \in dcl(c_i)$ so $A' \subseteq acl((c_j)_{j \in J})$. Thus $T_{A'}$ is $V$-minimal. So (1,2) applies and prove (3).

See Lemma 3.60 for a uniqueness statement.

Corollary 3.52. Let $f : VF \rightarrow (RV \cup \Gamma)^*$ be a definable map.

1. There exists a definable $\bar{f} : RV \rightarrow (RV \cup \Gamma)^*$ such that for any $x \in RV$, for some $x \in VF$ with $rv(x) = x$, $\bar{f}(x) = f(x)$.

2. Let $\Omega = VF/M$. There exists a definable map $\bar{f} : \Omega \rightarrow (RV \cup \Gamma)^*$ such that for any $x \in \Omega$, for some $x \in VF$ with $x + M = x$, $\bar{f}(x) = f(x)$.

Proof. (1) In view of Lemma 2.3, it suffices to show that for a given complete type $P \subseteq RV$, there exists such a function $\bar{f}$ on $P$. We fix $a \in P$, and show the existence of $c \in dcl(a)$ such that for some $a$ with $rv(a) = a$, $f(a) = c$.

By Proposition 3.51, there exists an effective substructure $A$ with $a \in A$ and $(RV \cup \Gamma)(A) = (RV \cup \Gamma)(< a >)$. Thus the open ball $rv^{-1}(a)$ has an $A$-definable point $a$. Set $c = f(a)$; since $f(a) \in RV(A) = RV(< a >)$ we have $c = f_P(a)$ for some definable function $f_P$. Clearly $f_P$ satisfies the lemma for the input $a$, hence for any input from $P$.

The proof of (2) is identical, using Lemma 3.51 (3). □

Corollary 3.53. Let $T$ be $V$-minimal. Assume every definable point of $\Gamma$ lifts to an algebraic point of $RV$. Then there exists a resolved structure $E_{rel}$ such that $E_{rel}$ can be embedded into any resolved structure $E$, and $RV(E_{rel})/\Gamma(E_{rel}) \subseteq dcl(\emptyset)$. If $A$ is a finitely generated substructure of a model of $T$, in the sorts $VF \cup \mathcal{B}$, the same is true for $T_A$.

Proof. Under the assumption of the corollary, the conclusion of Proposition 3.51 implies $RV(E_{rel}) \subseteq dcl(\emptyset)$. □

Remark 3.54. It is easy to see using the description of imaginaries in [16] that in a resolved structure, any definable $ACVF$-imaginary is resolved. In other words, if $A$ is a resolved, and $\sim$ is a definable equivalence relation on a definable set $D$, then $D(A) \rightarrow (D/\sim)(A)$ is surjective.

If $A$ is only effective, then there exists $\gamma \in \Gamma(A)^n$ such that for any $t$ with $val(t) = \gamma$, $(D/\sim)(A) \subseteq dcl(D(A)/\sim,t)$; this can be seen by embedding $D/\sim$ into $B_n(K)/H$ for an appropriate $H \leq B_n(O)$, and splitting $B_n = T_n U_n$.

3.8. Dimensions. We define the $VF$-dimension of a $T_M$-definable set $X$ to be the smallest $n$ such that for some $n$, $X$ admits a $T_M$-definable map with finite fibers into $VF^n \times (RV \cup \Gamma)^*$.

By essential bijection $Y \rightarrow Z$ we mean a bijection $Y_0 \rightarrow Z_0$, where $dim_{VF}(Y \setminus Y_0) < dim_{VF}(Z \setminus Z_0)$, and where two such maps are identified if they agree away from a set of dimension $< dim_{VF}(Y)$.

We say that a map $f : X \rightarrow VF^n$ has RV-fibers if there exists $g : X \rightarrow (RV \cup \Gamma)^*$ with $(f,g)$ injective.

Lemma 3.55. Let $X \subseteq VF^n \times (RV \cup \Gamma)^*$ be a definable set. Then

1. $X$ has $VF$-dimension $\leq n$ iff there exists a definable map $f : X \rightarrow VF^n$ with RV-fibers.
(2) If it exists, the map \( f \) is “unique up to isogeny”: if \( f_1, f_2 : X \to VF^n \) have RV-fibers, then there exists a definable \( h : X \to Z \subseteq VF^n \times (RV \cup \Gamma)^* \) and \( g_1, g_2 : Z \to VF^n \) with finite fibers, such that \( f_i = g_i h \).

Proof. (1) If \( f : X \to VF^n \) has RV-fibers, let \( g \) be as in the definition of RV-fibers; then \( (f, g) : X \to VF^n \times (RV \cup \Gamma)^* \) is injective, so certainly finite-to-one. If \( \phi : X \to VF^n \times RV^* \) is finite-to-one, by Lemma 3.9, each fiber \( \phi^{-1}(c) \) admits a \( c \)-definable injective map \( \psi_c : \phi^{-1}(c) \to RV^* \). By Lemma 2.3 we can find \( \theta : X \to VF^n \to RV^* \) that is injective on each \( \phi \)-fiber. Let \( f(x) = (\phi, \theta) \). This proves the equivalence.

(2) Now suppose \( f_1, f_2 : X \to VF^n \) both have RV-fibers.

Let \( h(x) = (f_1(x), f_2(x)) \), \( Z' = h(X) \), and define \( g_1 : Z' \to VF^n \) by \( g_1(x, y) = x \), \( g_2(x, y) = y \). Then \( g_1 \) has finite fibers. Otherwise we can find \( a \in X \) such that \( f_1(a) \notin acl(f_2(a)) \) (or vice versa.) But for any \( a \in X \), we have \( f_1(a) \in acl(f_2(a), c) \) for some \( c \in (RV \cup \Gamma)^* \). By Lemma 3.41, \( f_1(a) \notin acl(f_2(a)) \), a contradiction. By Lemma 3.36 (cf. Lemma 2.3), there exists a definable bijection between \( Z' \) and a subset \( Z \) of \( VF^n \times RV^* \). Replacing \( Z \) by \( Z' \) finishes the proof of the lemma.

\[ \square \]

Corollary 3.56. Let \( f : X \to RV \cup \Gamma, X_a = f^{-1}(a) \). Then \( \dim(X) = \max_a \dim X_a \).

Proof. Let \( n = \max_a \dim X_a \). For each \( a \) there exist definable functions \( g_a : X_a \to VF^n \) and \( h_a : X_a \to (RV \cup \Gamma)^* \) with \( (g_a, h_a) \) injective on \( X_a \). Thus by the compactness argument of Lemma 2.3, there exists a definable functions \( g : X \to VF^n \) and \( h : X_a \to (RV \cup \Gamma)^* \) such that \( (g, h) \) is injective when restricted to each \( X_a \). But then clearly \( (g, h, f) \) is injective, so \( \dim(X) \leq n \). The other inequality is obvious. \[ \square \]

We continue to assume \( T \) is \( V \)-minimal.

Lemma 3.57. Let \( a, b \in VF \). If \( a \in acl(b) \setminus acl(\emptyset) \) then \( b \in acl(a) \).

Proof. Suppose \( b \notin acl(a) \). Let \( A_0 = \Gamma acl(a, b) \). Then by Lemma 3.36, \( b \notin acl(A_0(a)) \).

Let \( C \) be the intersection of all \( acl(A_0) \)-definable balls such that \( b \in C \), and let \( C' \) be the union of all \( acl(A_0) \)-definable proper sub-balls of \( C \). Let \( B = \cap_i \{ B_i \} \) be the set of all balls defined over \( acl(A_0(a)) \) with \( b \in B_i \), and let \( B' = \cup_j \{ B_j \} \) be the union of all \( acl(A_0(a)) \)-definable proper sub-balls of \( B \).

Since \( a \in acl(b) \), we have \( a \in acl(b') \) for all \( b' \in B \setminus B' \), outside some proper sub-ball. It follows by compactness that for some \( i, j \), \( a \in acl(b') \) for all \( b' \in B_i \setminus B_j \). Say \( i = j = 1 \), \( B_1 \subseteq B_1 \). By Example 3.57, \( a \in acl(A_0(f_1)) \) where \( f_1 \in \mathcal{B} \) codes the ball \( B_1 \).

If \( B_1 \) is a point, we are done. Otherwise \( B_1 \) has valutative radius \( \alpha_1 < \infty \) defined over \( A_0 \). It follows that if \( B_1 \supseteq C \) then \( B_1 \) is \( acl(A_0) \)-definable; but then \( a \in acl(A_0) \), contradicting the assumption. Since \( B_1 \) meets \( P \) nontrivially, we have therefore \( B_1 \subset C \). Similarly \( B_1 \) cannot contain any ball in \( C' \) since it is not \( acl(A_0) \)-definable, but it cannot be contained in \( C' \) since \( B_1 \cap P \neq \emptyset \), so \( B_1 \cap C' = \emptyset \). Thus \( B_1 \subset P \).

Let \( \overline{B} \) be the closed ball of radius \( \alpha_1 \) containing \( B_1 \), and let \( e_1 \) be the corresponding element of \( \mathcal{B}_0 \). Since \( \overline{B} \) is almost definable over \( A_0(a) \), it follows from \( V \)-minimality that there exists an almost \( A_0(a) \)-definable point \( c(a) \) in \( \overline{B} \). Now if \( a \in acl(A_0(e_1)) \), then \( \overline{B_1} \) contains an \( A_0(e_1) \)-definable finite set \( F_1 = F_1(e_1) \). But since \( B_1 \) is a proper subset of \( P \), \( e_1 \notin acl(A_0) \). This contradicts Lemma 3.8. So \( a \notin acl(A_0(e_1)) \).

Nevertheless we have seen that \( a \in acl(A_0(f_1)) \). Thus \( B_1 \neq \overline{B_1} \), so \( B_1 \) is a maximal open sub-ball of \( \overline{B_1} \). Let \( b_1 \) be the point of \( \text{Aff}(\overline{B_1}) \) representing \( B_1 \). Then \( a \in acl(b_1) \). It follows that \( tp(a/\text{acl}(A_0(e_1))) \) is strongly minimal, contradicting Lemma 3.13. We have obtained a contradiction in all cases; so \( b \in acl(a) \). \[ \square \]
Since the lemma continues to apply over any VF-generated structure, algebraic closure is a
dependence relation in the sense of Steinitz (also called a pre-matroid or combinatorial geometry,
cf. [33].) Define the VF-transcendence degree of a finitely generated structure \( B \) to be the
maximal number of elements of \( \text{VF}(B) \) that are algebraically independent over \( \text{VF}(A) \). This is
the size of any maximal independent set, and also the minimal size of a subset whose algebraic
 closure includes all VF-points. Hence:

**Corollary 3.58.** The VF dimension of a definable set \( D \) is the maximal transcendence degree
of \( < b >. \)

We can now obtain a strengthening of Lemma 3.41, and a uniqueness statement in Proposition 3.51:

**Corollary 3.59.** Let \( Y \) be a \( T \)- definable set admitting a finite-to-one map \( f \) into \( \mathcal{B}^n \). Let
\( g : Y \to \mathcal{B}^m \) be a definable map. Then \( g(Y) \) is finite.

**Proof.** We may assume \( m = 1 \). We will use the equivalence (3) \( \iff (4) \) of Lemma 2.6. If
\( g(Y) \) is infinite, then by compactness there exists \( a \in g(Y) \) \( a \notin \text{acl}(A) \). But for some \( b \) we have
\( a = g(b) \), so if \( c = f(b) \), we have \( c \in \mathcal{B}^n \), \( a \in \text{acl}(c) \). Thus it suffices to show:

(*) If \( a \in \text{VF}, c \in \mathcal{B}^n \) and \( a \in \text{acl}(A(c)) \), then \( a \in \text{acl}(A) \).

This clearly reduces to the case \( n = 1, c \in \mathcal{B} \). Let \( \gamma \) be the valuative radius of \( c \). As follows
from Corollary 3.36, it suffices to show that \( a \in \text{acl}(A(\gamma)) \). So in (*) we may assume \( \gamma \in A \).

Finally, to prove (*) (using again the equivalence of Lemma 2.6), we may enlarge \( A \), so we
may assume \( A \models T \).

Since \( \gamma \in A \), \( c \in \text{dcl}(A(e)) \) for any element \( e \) of the ball \( c \). Thus \( a \in \text{acl}(A(e)) \). Suppose
\( a \notin \text{acl}(A) \); then by exchange for algebraic closure in VF, \( c \in \text{acl}(A(a)) \). Thus any two elements
of the ball \( c \) are algebraic over each other. By Example 2.4, \( c \) has finitely many points; which
is absurd. This contradiction shows that \( a \in \text{acl}(A) \).

**Lemma 3.60.** (cf. Proposition 3.51.) Let \( T \) be a finitely generated extension of an effective
V-minimal theory. Then if \( E_1, E_2 \) are effective and both embed into any effective \( E \), then they
are finitely generated, and \( E_1 \simeq E_2 \).

**Proof.** The finite generation is clear. Since \( E_1, E_2 \) embed into each other, they have the same
VF-transcendence degree We may assume \( E_1 \leq E_2 \). But then by Lemma 3.58, \( E_2 \subseteq \text{acl}(E_1) \).
By Lemma 3.9, \( E_2 \subseteq \text{dcl}(E_1, F) \) for some finite \( F \subseteq \text{RV}^n \cap \text{dcl}(E_2) \). But \( \text{RV}(E_1) = \text{RV}(E_2) \),
so \( F \subseteq \text{dcl}(E_1) \), and thus \( E_2 = E_1 \).

**Remark 3.61.** The analogous statement is true for resolved structures. Note that if \( F \) is a
finite definable subset of \( \text{RV}^n \) then automatically the coordinates of the points of \( F \) lie in cosets
of \( k^\ast \) that have algebraic points.

**Remark** The hypothesis of Lemma 3.60 can be slightly weakened to: \( T \) is finitely generated
over a \( V \)-minimal theory, and there exists a finitely generated effective \( E \).

**Example 3.62.** In ACVF, when \( X \subseteq \text{VF}^n \), the VF-dimension equals the dimension of the
Zariski closure of \( X \). This is proved in [35]. The idea of the proof: the VF-dimension is clearly
bounded by the Zariski dimension. For the opposite inequality, in the case of dimension 0, if
\( X \) is a finite \( A \)-definable subset of \( VF \), then using quantifier elimination there exists a nonzero
polynomial \( f \) with coefficients in \( A \), such that \( f \) vanishes on \( X \). In general, if a definable
\( X \subseteq \text{VF}^n \) has VF dimension \( < n \), one can reduce to the case where all fibers of the projection
pr : X → pr.X ⊂ VF^{n-1} are finite, then X is not Zariski dense in VF^n, using the 0-dimensional case.

The RV\textsuperscript{-}dimension of a definable set X ⊆ RV\textsuperscript{*} is the smallest integer n (if any) such that X admits a parametrically definable finite-to-one map into RV^n. More generally for X ⊆ (RV ∪ Γ)^*,\, \dim_{RV}(X) is the smallest integer n (if any) such that X admits a parametrically definable finite-to-one map into (RV ∪ Γ)^n.

Note that RV is one-dimensional, but Γ and every fiber of val_r, are also one-dimensional. In this sense RV ∪ Γ\text{-}dimension is not additive; model-theoretically it is closer to weight than to rank. We do have \dim(X × Y) = \dim(X) + \dim(Y).

Dually, if a structure B is RV-generated over a substructure A, we can define the weight of B/A to be the least n such that B ⊆ acl(A, a_1, ..., a_n), with a_i ∈ RV.

For subsets of RV, RV\text{-}dimension can be viewed as the size of a Steinitz basis with respect to algebraic closure. One needs to note that the exchange principle holds:

**Lemma 3.63** (exchange). Let a, b_1, ..., b_n ∈ RV; assume a ∈ acl(A, b_1, ..., b_n) \ acl(A, b_1, ..., b_{n-1}). Then b_n ∈ acl(A, b_1, ..., b_{n-1}, a).

**Proof.** We may take n = 1, b_n = b, and A = acl(A). Let α = val_r(a) ∈ Γ, β = val_r(b). If β ∈ A then Γ(A(a, b)) = Γ(b) = Γ(A). The first equality is true since a ∈ acl(A(b)) so A(a, b) ⊆ acl(A(b)), and using the stable embeddedness of Γ (§2.1.5) and the linear ordering on Γ. The second equality follows from Lemma 3.10. So if β ∈ A then a, b lie in A-definable strongly minimal sets, cosets of k*, and the lemma is clear.

Assume β ∈ A, then tp(a/Γ) is strongly minimal, and tp(a/A) implies tp(a/A(b)) by Lemma 3.10; but then a ∈ acl(A), contradicting the assumption. So α, β ∉ A; from the exchange principle in Γ it follows that A' := acl(A, α) = acl(A, β). Moreover a ∉ acl(α) by Lemma 3.11 and Lemma 2.6. By the previous case, b ∈ acl(A', a), so b ∈ acl(A, a). □

**Lemma 3.64.** A definable X ⊆ RV^n has RV\text{-}dimension n iff it contains an n-dimensional definable subset of some coset of k^n*.

**Proof.** Assume X has RV\text{-}dimension n. Then there exists (a_1, ..., a_n) ∈ X with a_1, ..., a_n algebraically independent. Let c ∈ Γ; then since a_n ∉ acl(a_1, ..., a_{n-1}), it follows as in the proof of Lemma 3.63 that a_n ∉ acl(a_1, ..., a_{n-1}, c). This applies to any index, so a_1, ..., a_n remain algebraically independent over c_i and inductively we may add to the base any finite number of elements of Γ. Let c_i = val_r(a_i), and let A' = A(c_1, ..., c_n). Then a_1, ..., a_n are algebraically independent over A', and the lie in X' = X ∩ \Pi_{i=1}^n rv^{-1}(c_i); thus X' is an n-dimensional definable subset of a coset of k^n*.

**Definition 3.65.** VF[n, \cdot] be the category of definable subsets of VF^* × RV^* of dimension ≤ n. Morphisms are definable maps.

Let X ∈ Ob VF[n, \cdot] by Lemma 3.55, there exists a definable f : X → VF^n with RV-fibers; and the maximal RV\text{-}dimension of a fiber is a well-defined quantity, depending only on the isomorphism type of X (but not on the choice of f). In particular, the subcategory of definable sets of maximal fiber dimension 0 will be denoted VF[n].

**Definition 3.66.** We define RV[n, \cdot] to be the category of definable pairs (U, f), with U ⊆ RV^*, f : U → RV^n. If U, U' ∈ Ob RV[n, \cdot], a morphism h : U → U' is a definable map, such that U'' = \{(f(u), f'(h(u))) : u ∈ U\} has finite-to-one first projection to RV^n. RV[n] is the full subcategory of pairs (U, f) with f : U → RV^n finite-to-one.
RES[n] is the full subcategory of RV[n] whose objects are pairs (U, f) ∈ Ob RV[n] such that \( \text{val}_{RV}(U) \) is finite, i.e. \( U \subseteq \text{RES}^\ast \).

**Remark 3.67.**

1. For \( X, Y \in \text{Ob RV}[n] \), any definable bijection \( X \to Y \) is in \( \text{Mor}_{RV}[n](X,Y) \).

2. The forgetful map \( (X,f) \mapsto X \) is an equivalence of categories between RV[n] and the category of all definable subsets of RV* of RV-dimension \( \leq m \), with all maps between them. The presentation with \( f \) is nonetheless useful for defining \( L \).

By Remark 3.67 \( K_+(RV[m]) \) is isomorphic to the Grothendieck semigroup of definable subsets of RV* of RV-dimension \( \leq m \). If \( \dim(X) \leq m \), let \([X]_m \) denote the class \([X]_m = ([X,f])_m \in RV[m], \) where \( f : X \to RV^* \) is any finite-to-one definable map.

Unlike the case of VF[n, -] or RV[n, -], for \((U, f) \in \text{Ob RV}[n, -]\) the map \( f \) cannot be reconstructed from \( U \) alone, even up to isogeny, so it must be given as part of the data. We view \((U, f)\) as a cover of \( f(U) \) with “discrete” fibers.

We denote

\[
\text{RV}[\leq N, -] := \bigoplus_{0 \leq n \leq N} \text{RV}[n, -], \quad \text{RV}[\leq N] := \bigoplus_{0 \leq n \leq N} \text{RV}[n]
\]

\[
\text{RV}[*] := \bigoplus_{0 \leq n} \text{RV}[n, -], \quad \text{RES}[*] := \bigoplus_{0 \leq n} \text{RES}[n]
\]

We have natural multiplication maps \( K_+\text{RV}[k, -] \times K_+\text{RV}[l, -] \to K_+\text{RV}[k+l, -] \), \( ([X, f], [(Y, g)]) \to [(X \times Y, f \times g)] \). This gives a semiring structure to \( K_+(\text{RV}[*]) \). This differs from the Grothendieck ring \( K_+(\text{RV}) \).

### 3.8.1. Alternative description of RV[\leq N, -]

An object of \( \text{RV}[\leq N, -] \) thus consists of a formal sum \( \sum_{n=0}^N X_n \) of objects \( X_n = (X_n, f_n) \) of \( \text{RV}[n, -] \). This can be explained from another angle if one adds a formal element \( \infty \) to \( \text{RV} \), and extends \( \text{rv} \) to \( \text{VF} \) by \( \text{rv}(\infty) = \infty \). Define a function \( f[k] \) by \( f[k](x) = (f_n(x), \infty, \ldots, \infty) \) \( (N-k \text{ times}) \). If \( X = (X, f) \), let \( X[k] = (X, f[k]) \). Then \( \sum_{n=0}^N X_n \) can be viewed as the disjoint union \( \bigcup_{n=0}^N X_n \times \{\infty\} \) [\( N - i \)]. The \( \text{rv} \) pullback is then a set of VF-dimension \( N \), invariant under multiplication by \( 1 + \mathcal{M} \); the sum over dimensions \( \leq N \) is necessary to ensure that any such invariant set is obtained. (Cf. Lemma 4.9.) From this point of view, an isomorphism is a definable bijection preserving the function “number of finite coordinates”. We will use \( \text{RV}[\leq N, -] \) or \( \text{RV}[\leq N, -] \) interchangeably.

**Lemma 3.68.** Let \( X, X' \in \text{Ob RV}[n, -] \), and assume a bijection \( g : X' \to X \) lifts to \( G : LX' \to LX \). Then \( g \in \text{Mor}_{\text{RV}[n, -]}(X', X) \).

**Proof.** We only have to check the isogeny condition, i.e. that \( f(g(a)) \in \text{acl}(f'(a)) \) for \( a \in X' \) (and dually). By Lemma 3.42, for \( x \in \rho_{X'}^{-1}(a) \), \( G(x)_{VF} \in \text{acl}(x_{VF}) \), i.e. the VF-coordinates of \( G(x) \) are algebraic over those of \( x \). Thus \( f(g(a)) \in \text{acl}(x_{VF}) \). This is true for any \( x \in \rho_{X'}^{-1}(a) \), so \( f(g(a)) \in \text{acl}(a) \).

4. Descent to RV: objects

We assume \( T \) is \( C \)-minimal with centered closed balls. We will find a very restricted set of maps that transform any definable set to a pullback from RV. This is related to Denef’s cell decomposition theorem; since we work in \( C \)-minimal theories it takes a simpler form. Recall that this assumption is preserved under passage to \( T_A \), when \( A \) is a \((VF, RV, \Gamma)\)-generated substructure of a model of \( T \) (Lemma 3.39).

Recall that \( RV = VF^X/(1 + \mathcal{M}) \), \( rv : VF^X \to RV \) the quotient map. Let \( RV_{\infty} = RV \cup \{\infty\} \), and define \( \text{rv}(0) = \infty \). We will also write \( rv \) for the induced map \( rv^n : (VF^X)^n \to (RV)^n \).
Definition 4.1. Fix n. Let \( \mathcal{C}^0 \) be the category whose objects are the definable subsets of \( VF^n \times RV_{\infty}^+ \), and whose morphisms are generated by the inclusion maps together with functions of one of the following types:

1. **Maps**

\[
(x_1, \ldots, x_n, y_1, \ldots, y_l) \mapsto (x_1, \ldots, x_{i-1}, x_i + a, x_{i+1}, \ldots, x_n, y_1, \ldots, y_l)
\]

with \( a = a(x_1, \ldots, x_{i-1}, y_1, \ldots, y_l) :VF^{i-1} \times RV_{\infty}^i \rightarrow VF \) an \( A \)-definable function of the coordinates \( y_1, x_1, \ldots, x_{i-1} \).

2. **Maps**

\[
(x_1, \ldots, x_n, y_1, \ldots, y_l) \mapsto (x_1, \ldots, x_n, y_1, \ldots, y_l, rv(x_i))
\]

The above functions are called **elementary admissible transformations** over \( A \); a morphism in \( \mathcal{C}^0_\mathcal{A} \) generated by elementary admissible transformations over \( A \) will be called an **admissible transformation** over \( A \). Taking \( l = 0 \), we see that all \( A \)-definable additive translations of \( VF^n \) are admissible.

Analogously, if \( Y \) is a given definable set, one defines the notion of a \( Y \)-family of admissible transformations.

If \( e \in RV \) and \( T_e \) is an \( A(e) \)-admissible transformation, then there exists an \( A \)-admissible \( T \) such that \( T_e T = T e \), where \( \nu(x_1, \ldots, x_n, y_1, \ldots, y_l) = (x_1, \ldots, x_n, e, y_1, \ldots, y_l) \). This is easy to see for each generator and follows inductively.

Informally, note that admissible maps preserve volume for any product satisfying Fubini’s theorem of translation invariant measures on \( VF \) and counting measures on \( RV \).

We will now see that any \( X \subset VF^n \) is a finite disjoint union of admissible transforms of pullbacks from \( RV \). We begin with \( n = 1 \).

**Lemma 4.2.** Let \( T \) be \( C \)-minimal with centered closed balls. Let \( X \) be a definable subset of \( VF \). Then \( X \) is the disjoint union of finitely many definable sets \( Z_i \), such that for some definable transformations \( T_i \) and definable subsets \( H_i \) of \( RV_{\infty}^i \), \( T_i Z_i = \{(x, y) : y \in H_i, rv(x) = y_i\} \).

If \( X \) is bounded, \( H_i \) is bounded below; in fact for any \( h \in H_i \), \( rv(h) \geq \text{val}(x) \) for some \( x \in X \).

Here \( VF \) will be considered a ball of valuative radius \(-\infty\), points as balls of valuative radius \( \infty \).

**Proof.** We may assume \( X \) is a finite union of disjoint balls of the same valuative radius \( \alpha \in \Gamma \cup \{\pm \infty\} \), each minus a finite union of proper sub-balls, since any definable set is a finite union of definable sets of that form.

**Case 1** \( X \) is a closed ball.

In this case, by the assumption of centered closed balls, \( X \) has a definable point \( a \). Let \( T(x) = x - a \). Then \( TX \setminus \{0\} \) is the pullback of a subset of \( \Gamma \), the semi-infinite interval \([\alpha, \infty)\)

(where \( \alpha \) is the valuative radius of \( X \)). Thus \( TX = rv^{-1}(H) \) where \( H = val_{rv}^{-1}((\alpha, \infty)) \cup \{\infty\} \).

**Case 2** \( X \) is an open ball.

Let \( X \) be the surrounding closed ball of the same radius \( \alpha \), and as in Case 1 let \( a \in X \) be a definable point, \( T(x) = x - a \). If \( 0 \in TX \) then \( TX = rv^{-1}(H) \) where \( H = val_{rv}^{-1}((\alpha, \infty)) \cup \{\infty\} \).

If \( 0 \notin TX \), then \( TX = rv^{-1}(H) \) where \( H = rv(TX) \) is a singleton of \( RV \).

**Case 3** \( X = C \setminus F \) is a ball with a single hole, the closed ball \( F \).

Let \( \beta \) be the valuative radius of \( F \). Let \( a \in F \) be a definable point, \( T(x) = x - a \). Then \( TX = rv^{-1}(H) \), \( H = val_{rv}^{-1}(I) \), where \( I \) is the open interval \((\alpha, \beta)\) of \( \Gamma \) in case \( C \) is closed, the half-open interval \([\alpha, \beta)\) when \( C \) is open.

**Case 4** \( X = C \setminus \bigcup_{j \in J} F_j \) is a closed ball, minus a finite union of maximal open sub-balls.
As in Case 1, find $T_i$ such that $0 \in T_i X$. Then $T_i X$ is the union of the maximal open sub-ball $S$ of radius $\alpha$, with $\text{rv}^{-1}(H)$, where $H = \text{rv}(X \setminus S)$. $S$ can be treated as in Case 2.

Here $H$ is a subset of $\text{val}_{\text{rv}}^{-1}(\alpha)$, consisting of $\text{val}_{\text{rv}}^{-1}(\alpha)$ minus finitely many points.

**Cases 3a, 4a:** $X$ is a union of $m$ balls (perhaps with holes) of types 1-4 above.

Here we use induction on $m$; we have $m$ balls $C_j$ covering $X$. Let $E$ be the smallest ball containing all $C_j$. As we may assume $m > 1$, $E$ must be a closed ball; and each $C_j$ is contained in some maximal open sub-ball $M_j$ of $E$. By the choice of $E$, not all $C_j$ can be contained in the same maximal open ball of $E$. Let $a \in E$ be a definable point, $T_i(x) = x - a$. If $0 \in T_i C_j$ for some $j$, the lemma is true by induction for this $C_j$ and for the union of the others, hence also for $X$. Otherwise, $F = \text{rv}(T_i(X))$ is a finite set, with more than one element. For $b \in F$, let $Y_b = T_i X \cap \text{rv}^{-1}(b)$. By Lemma 2.3, we can in fact find a definable $Y$ whose fiber at $b$ is $Y_b$.

By induction again, there exists an admissible transformation $T_b$ such that $T_b(Y)$ is a pullback of the required form. Let $T_3(x) = (x, rv(x))$, $T_3((x, b)) = ((T_b(x), b))$. Then $T_3 T_2 T_1$ solves the problem.

**General subsets of VF**

Let $\beta > \alpha$ be the least size (i.e., greatest element of $\Gamma$) such that some ball of radius $\beta$ contains more than one hole of $X$. Let $\{C_j : j \in J\}$ be the balls of radius $\beta$ around the holes $W$ of $X$, and let $C = \bigcup_{j \in J} C_j$. Then $X = (X \setminus C) \cup (C \setminus W)$. Now $X \setminus C$ has fewer holes than $X$, so it can be dealt with inductively. Thus we may assume $X = C \setminus W$; and any proper sub-ball of $C$ of less than maximal size contains at most one hole of $X$. We may assume the $\{C_j\}$ form a single Galois orbit; so they each contain two or more holes of $X$. Since these holes are not contained in a proper sub-ball of $C_j$, each $C_j$ must be closed, and the maximal open sub-balls of $C_j$ separate holes.

Let $D_{j,k}$ be the maximal open sub-balls of $C_j$ containing a hole $F_{j,k}$. Let $\tilde{F}_{j,k}$ be the smallest closed ball containing $F_{j,k}$. Then $X = (C \setminus \bigcup_{j,k} D_{j,k}) \cup \bigcup_{j,k} (D_{j,k} \setminus \tilde{F}_{j,k}) \cup \bigcup_{j,k} \tilde{F}_{j,k} \setminus F_{j,k}$.

The second summand in this union falls into Case 3a, the first and third (when non-empty) into case 4a.

\[\square\]

**Remark** If we allow arbitrary Boolean combinations (rather than disjoint unions only), we can demand in Lemma 4.2 that the sets $H_i$ be finite. More precisely, let $X$ be a definable subset of $\text{VF}$. Then there exist definable sets $Z_i$, admissible transformations $T_i$, and finite definable subsets $H_i$ of $\text{RV}_{\infty}^\perp$ such that:

- $X$ is a Boolean combination of the sets $Z_i$, and $T_i Z_i$ is one of the following:
  1. $\text{VF}$
  2. $(0) \times H_i$
  3. $b_i \times H_i$, with $b_i$ a definable ball containing 0
  4. $\{(x, y) : y \in H_i, \text{rv}(x) = f_i(y)\}$, for some definable function $f_i : H_i \to \text{RV}_{\infty}$

**Corollary 4.3.** Let $X \subseteq \text{VF} \times \text{RV}^*$ be definable. Then there exists a definable $\rho : X \to \text{RV}^*$ and $c : \text{RV}^* \to \text{VF}$, $c' : \text{RV}^* \to \text{RV}_{\infty}$, $c'' : \text{RV}^* \to \text{RV}^*$ such that every fiber $\rho^{-1}(a)$ has the form $(c(a) + \text{rv}^{-1}(c'(a))) \times \{c''(a)\}$. Moreover $c$ has finite image.

**Proof.** The finiteness of the image of $c$ is automatic, by Lemma 3.41. The corollary is obviously true for sets of the form $L(H, h) = \{(x, u) \in \text{VF} \times H : \text{rv}(x) = h(u)\}$; take $\rho(x, u) = (\text{rv}(x), u)$. If the statement holds for $TX$ where $T$ is an admissible transformation, then it holds for $X$. If true for two disjoint sets, it is also true for their union (add to $\rho$ a map to $\{1, -1\} \subseteq k^*$ whose fibers are the two sets.) Hence by Lemma 4.2 is it is true for all definable sets. \[\square\]

**Corollary 4.4.** Let $T$ be $V$-minimal, $X \subseteq \text{VF}$ and let $f : X \to \text{RV} \cup \Gamma$ be a definable function. Then there exists a definable finite partition of $X = \bigcup_{i=1}^m X_i$ such that either $f$ is constant on
$X_i$, or else $X_i$ is a finite union of balls of equal radius (possibly missing some sub-balls), there is a definable set $F_i$ meeting each of the balls $b$ in a single point, and for $x \in X_i$, letting $n(x)$ be the point of $F_i$ nearest $x$, for some function $H$, $f(x) = H(rv(x - n(x)))$.

Proof. The conclusion is so stated that it suffices to prove it over $\text{acl}(\emptyset)$, i.e. we may assume every almost definable set is definable; cf. §2.1.4. By compactness it suffices to show that for each complete type $p$, $f[p]$ has the stated form. Let $b$ be the intersection of all balls containing $p$. If $b$ is transitive then by Lemma 3.47 $f[p]$ is constant. Otherwise by V-minimality $b$ contains a definable point, and so we may assume $0 \in b$. It follows that $rv(p)$ is infinite. Thus by Lemma 3.20, $f$ factors through $rv$. □

Proposition 4.5. Let $T$ be $C$-minimal with centered closed balls, and let $X$ be a definable subset of $VF^n \times RV^l$. Then $X$ can be expressed as a finite disjoint union of $A$-definable sets $Z_i$, for each $Z$ of the following form. For some $A$-admissible transformation $T$, $A$-definable subset $H$ of $RV^l$, and map of indices $\nu \in \{1, \ldots, n\} \mapsto \nu' \in \{1, \ldots, n'\}$,

$$TZ = \{(a, b) : b \in H, rv(a_{\nu}) = b_{\nu'} (\nu = 1, \ldots, n)\}$$

If $X$ projects finite-to-one to $VF^n$, then the projection of $H$ to the primed coordinates $1', \ldots, n'$ is finite to one.

If $X$ is bounded, then $H$ is bounded below in $RV^l$.

Proof. By induction on $n$; the case $n = 0$ is trivial. Let $pr : X \rightarrow prX$ be the projection of $X$ to $VF^{n-1} \times RV^l$, so that $X \subseteq VF \times prX$.

Let $pr^*(Y) = \{v : (\exists y \in Y)(x, y) \in Y\}$. For any $c \in prX$, according to Lemma 4.2, we can write $pr^*(c) = \bigcup_{i=1}^k Z_i(c)$, where

$$T_i(c)Z_i(c) = \{(a, b) : b \in H_i(c), rv(a) = b_{\nu'}\}$$

for some $A(c)$-admissible $T_i(c)$, $A(c)$-definable $Z_i(c)$, and $H_i(c) \subseteq RV = RV^l$. We can write $Z_i(c) = \{x : (x, c) \in Z_i\}$, $H_i(c) = \{x : (x, c) \in H_i\}$ for some definable $Z_i$ and $H_i \subseteq VF^{n-1} \times RV^l$. By compactness, as in Lemma 2.3, one can assume that the $Z_i(c)$, $H_i(c)$, $T_i(c)$ are uniformly definable; there exists a partition of $prX$ into finitely many definable sets $Y$, and for each $Y$ families $Z_i, H_i, T_i$ over $Y$ of definable sets and admissible transformations over $Y$, such that the integer $k$ is the same for all $c \in Y$, and the $Z_i(c), H_i(c), T_i(c)$ are fibers over $c$ of $Z_i, H_i, T_i$. In this case, $pr^*(Y) = \bigcup_{i=1}^k Z_i$. We can express $X$ as a disjoint union of the various $pr^*(Y)$; so we may as well assume $prX = Y$ and $X = Z_i$. Let $T_i$ be such that $\iota_c T_i(c) = T_{i\iota c}$. Then

$$T_iX = \{(a, c, b) : (c, b) \in H_i, rv(a) = b_{\nu'}\}$$

Any admissible transformation is injective and so commutes with disjoint unions.

Now by induction, $H_i$ itself is a disjoint union $H_i = \bigcup_{j=1}^{k'_i} Z_j$, with

$$T'_i Z'_i = \{(d, b) : b \in H'_i, rv(d_{\nu}) = d_{\nu'} (\nu = 2, \ldots, n)\}$$

Notational remarks: Here $d = (d_2, \ldots, d_n)$ are the VF-coordinates of $c$ above. The $'$ depends on $i$ but we will not represent this notationally.

Let $T'_i(a, d, b) = (a, T'_i(d, b))$, i.e $T'_i$ does not touch the first coordinate. Note that $T'_i$ also does not move the $1'$ coordinate, since in general admissible transformations can only add $RV$ coordinates but not change existing ones. Let

$$Z_i = \{x : T_i(x) = (a, d, b), (d, b) \in Z'_i, rv(a) = b_{\nu'}\}$$
Then (as one sees by applying $T_1$) $X = \bigcup_{i=1}^k Z_i$, and if $T_i = T_i^* T_1$, we have:

$$T_i Z_i = \{(a, d', b') : (d', b') \in T_i^* Z_i, \text{rv}(a) = b'_i \} = \{(a, d', b') : b \in H_i, \text{rv}(a) = b_i, \text{rv}(d) = b_i' \}$$

As for the finiteness of the projection, if $X$ admits a finite-to-one projection to $\text{VF}^n$, so does each $Z$ in the statement of the Proposition, and hence the isomorphic set $T Z$. We have $H \subset \text{RV}^n+^t$, $\pi : \text{RV}^n+^t \to \text{RV}^n$, so $T Z = \{(a, b, b') : (b, b') \in H, \text{rv}(a) = b' \}$. For fixed $a$, this yields an $a$-definable finite-to-one map $T Z'(a) = \{(b') : (a, b, b') \in T Z \to \text{VF}^n$. By Lemma 3.41, $T Z'(a)$ is finite. Now fix $b$ and suppose $(b, b') \in H$ with $b'$ not algebraic over $b$. Then for generic $a \in \text{rv}^{-1}(b)$, $b'$ is not algebraic over $b, a$. Yet $(a, b, b') \in T Z$ and so $b' \in T Z'(a)$, a contradiction.

The statement on boundedness is obvious from the proof; if $X \subseteq \{ x : \text{val}(x) \geq -\gamma \}^n \times \text{RV}^m$, then $H$ is bounded below by $-\gamma$ in each coordinate.

\[ \square \]

4.0.2. A remark on more general base structures.

**Lemma 4.6.** Let $T$ be $V$-minimal, $A$ an $\mathcal{B}$-generated substructure of a model of $T$. Let $X$ be a $T_A$-definable subset of $\text{VF}^n \times \text{RV}^l$. Then there exist $T_A$-definable subsets $Y_i \subset \text{RV}^{m_i}$ and (projection) maps $f_i : Y_i \to \text{RV}^n$, a disjoint union $Z$ of

$$Z_i = Y_i \times f_i^{\text{rv}} \text{VF}^n$$

and a nonempty $A$-definable family $\mathcal{F}$ of admissible transformations $X \to Z$. $\mathcal{F}$ will have an $A'$-point for any $\text{VF} \cup \text{RV} \cup \Gamma$-generated structure containing $A$.

\[ \cdot \]

**Proof.** We may assume $A$ is finitely generated. By Proposition 3.51 there exists an almost $\text{VF} \cup \Gamma$-generated $A' \supset A$ embeddable over $A$ into any $\text{VF} \cup \Gamma$-generated structure containing $A$, and with $\text{RV}(A') = \text{RV}(A)$. By Proposition 4.5, the required objects $Y_i, f_i$ exist over $A'$. But since $\text{RV}$ is stably embedded, this data is defined over $\text{RV}(A') \subseteq A$. The admissible transformations $X \to Z = \bigcup (Y_i \times f_i^{\text{rv}}, \text{VF}^n)$ exist over $A'$; so one can find a definable set $D$ with an $A'$-point, and such that any element of $D$ codes an admissible transformation $X \to Z$. \[ \square \]

**Remark** In fact, arbitrary $\text{ACVF}$-imaginaries may be allowed here.

**Example 4.7.** $\mathcal{F}$ need not have an $A$-rational point. For instance if $A$ consists of an element of $\text{VF}/\mathcal{M}$, i.e. an open ball $c$, then we can take $Y = Y_1$ to be the point $0 \in \text{RV}$ (since $c$ can be transformed to $\mathcal{M}$); but there is no $A$-definable bijection of $c$ with $\mathcal{M}$.

4.0.3. A statement in terms of Grothendieck groups. Recall definitions 3.65, 3.66.

**Definition 4.8.** Define $L : \text{Ob RV}[n, -] \to \text{Ob VF}[n, -]$ by:

$$L(X, f) = (\text{VF}^\times )^n \times_{f^{\text{rv}}} X \subset \text{VF}^n \times \text{RV}^m$$

where $\text{VF}^\times = \text{VF} \setminus \{0\}$.

For $X = \sum_i X_i \in \text{RV}[*, ]$, we let $L(X)$ be the disjoint sum $\sum_i L(X_i)$ over the various components in $\text{RV}[*]$. Let $p$ denote the natural map $L(X, f) \to X$.

**Lemma 4.9.** The image of $L : \text{Ob RV}[\leq n, -] \to \text{Ob VF}[n, -]$ meets every isomorphism class of $\text{VF}[n, -]$.
Proof. For $X \subseteq RV^*$ and $f : X \rightarrow RV_\infty$, define $rv(0) = \infty$ and

$$L(X, f) = VF^n \times_{rv^*} f X \subset VF^n \times RV^m$$

Then in the statement of Proposition 4.5, we have $TZ = L(H, h)$ where $h$ is the projection to the primed coordinates. For $x \in H$, let $s(x) = \{ i : h_i(x) = \infty \}$. For $w \subseteq \{ 1, \ldots, n \}$, let $H_w = \{ x \in H : s(x) = w \}$. Let $\tilde{H}_w = (H_w, h_w)$ where $h_w = (h_i)_{i \notin w}$. Then $\tilde{H}_w \in RV[|w|, 1]$, and $L(H_w, h)|H_w| \simeq L(\tilde{H}_w)$. So $L(H, h) \simeq L(\sum_w \tilde{H}_w)$. □

4.0.4. A restatement in terms of VF alone. This restatement will not be used later in the paper.

Definition 4.10. Let $A$ be a subfield of VF. Let $\mathcal{C}^i_A(n, l)$ be the category of definable subsets of $VF^n \times (VF^\times)^l$, generated by composition and restriction to subsets by maps of one of the following types:

1. Maps

$$(x_1, \ldots, x_n, y_1, \ldots, y_l) \mapsto (x_1, \ldots, x_{i-1}, x_i + a, x_{i+1}, \ldots, x_n, y_1, \ldots, y_l)$$

with $a = a(x_1, \ldots, x_{i-1}, y_1, \ldots, y_l) : VF^{i+l-1} \rightarrow VF$ an $A$-definable function of the coordinates $y_1, \ldots, y_l$.

2. Maps

$$(x_1, \ldots, x_n, y_1, \ldots, y_l) \mapsto (x_1, \ldots, x_n, y_1, \ldots, y_{i-1}, x_i y_i, y_{i+1}, \ldots, y_l) : X \rightarrow Y$$

assuming $x_i \neq 0$ on $X$, and that this function takes $X$ into $Y$.

Remark 4.11. The morphisms in this category are measure preserving with respect to Fubini products of invariant measures (additively for VF, multiplicatively for $VF^\times$), viz. $dx_1 \wedge \cdots \wedge dx_n \wedge \frac{du_1}{y_1} \cdots \wedge \frac{du_l}{y_l}$.

Lemma 4.12. Let $T$ be $C$-minimal with centered closed balls, $X$ a definable subset of $VF^n$. Then $X$ can be expressed as a disjoint union of $A$-definable sets $Z$ with the following property. For some $l \in \mathbb{N}$, there exists an $\mathcal{C}^i_A(n, l)$-transformation $T$ and a definable subset $H$ of $RV_\infty^n \times RV^l$, such that

$$T(Z \times ((1 + M)^l)) = rv^{-1}(H)$$

Moreover, the projection of $H$ to $RV_\infty^n$ is finite-to-one.

If $val(x)$ is bounded below, then $val(H)$ may be taken to be bounded below in the RV-coordinates, and bounded in the $RV_\infty$-coordinates.

Proof. Proposition 4.5 □

5. V-minimal geometry: Continuity and Differentiation

We work with a $V$-minimal theory.

5.1. Images of balls under definable functions.

Proposition 5.1. Let $X, Y$ be definable subsets of VF, and let $F : X \rightarrow Y$ be a definable bijection. Then there exists a partition of $X$ to finitely many definable equivalence classes, such that for any open ball $b$ contained in one of the classes, $F(b)$ is an open ball; and dually, if $F(b)$ is an open ball, so is $b$.

Proof. It suffices to show that such a partition exists over acl(0); for any finite almost definable partition has a finite definable refinement (cf. discussion of Galois theory in §2.13). Thus as in §2.1.4 we may assume every almost definable set is named.

We will show that if $p$ is a complete type, and $b$ is an open sub-ball of $p$, then $F(b)$ is an open ball; and that if $b'$ is an open sub-ball of $F(p)$, then $b$ is an open ball. From this it follows by compactness that there exists a definable $D_p$ containing $p$ with the same property; by another
use of compactness, finitely many $D_p$ cover $X$; it then suffices to choose any partition, such that any class is contained in some $D_p$.

When $p$ has a unique solution, the assertion is trivial. When $p$ is the generic type of a closed ball, or of VF, or of a transitive open or $\infty$-definable ball, for any $\alpha \in \Gamma$, $p$ remains complete over $<\alpha>$. In the transitive cases, this follows from Lemma 3.47, while in the centered closed case it follows from Lemma 3.18.

Thus all open sub-balls $b_i$ of $p$ of any radius $\alpha$ have the same type over $<\alpha>$; hence they are all transitive over $<t>$, where $t \in K/M_\alpha$, where $M_\alpha = \{x: \text{val}(x) > \alpha\}$ (Lemma 3.8, with $Q = p$). Thus by Lemma 3.46, $F(b_i)$ is an open ball.

The remaining case is that $p$ is the generic type of a centered open or $\infty$-definable ball $b_1$. So $b_1$ contains a definable proper sub-ball $b_0$. If $b$ is an open sub-ball of $p$, of radius $\alpha$, then $b \cap b_0 = \emptyset$; let $\bar{b}$ be the smallest closed ball of containing $b$ and $b_0$. Then $b$ is contained in the generic type of $\bar{b}$, and so by the case of closed balls, $F(b)$ is an open ball.

**Remark 5.2.** When $X \subseteq VF \times RV^n$, by a ball contained in $X$ we will mean a subset of $X$ of the form $b \times \{e\}$, where $b \subseteq B$ and $e \in RV^n$. With this understanding, the proposition extends immediately to such sets $X$. Indeed for each $e \in RV^n$, according to the proposition there is a finite partition of $X(e)$ with the required property; as in Lemma 2.3 these can be patched to form a single partition of $X$.

**Remark 5.3.** When $X \subseteq VF$ there exists a finite set of points $F$ (not necessarily $A$-definable) such that $F(b)$ is an open ball whenever $b$ is an open ball disjoint from $F$. (This does not extend to $X \subseteq VF \times RV^n$.)

Indeed by Proposition 5.1 there is a finite number of closed and open balls $b_i$ and points, such that $F(b)$ is an open ball for any open ball $b$ that is either contained in or is disjoint from each $b_i$. Now let $c_i$ be a point of $b_i$. If $b$ is an open ball and no $c_i \in b$, then $b$ must be disjoint from, or contained in, each $b_i$; otherwise $b$ contains $b_i$, hence $c_i$.

5.2. Images of balls, II.

**Lemma 5.4.** Let $X,Y$ be balls, and $F: X \to Y$ a definable bijection taking open balls to open balls. Then for all $x,x' \in X$

$$\text{val}(F(x) - F(x')) = \text{val}(x - x') + \nu_0$$

where $\nu_0$ is the difference of the valuations radii of $X,Y$.

**Proof.** Translating by some $a \in X$ and by $F(a) \in Y$, we may assume $0 \in X, 0 \in Y$, $F(0) = 0$; and by multiplying we may assume and both $X,Y$ have valuation radius 0, i.e. $X = Y = 0$. Let $M(\alpha) = \{x: \text{val}(x) < \alpha\}$. Then $F(M(\alpha)) = M(\beta)$ for some $\beta = \beta(\alpha)$. $\beta$ is an increasing definable surjection from $\{\alpha \in \Gamma: \alpha > 0\}$ to itself; it must have the form $\beta(\alpha) = m\alpha$ for some rational $m > 0$. By Lemma 3.26, we have $m \in \Z$. Now reversing the roles of $X,Y$ and using $F^{-1}$ will transform $m$ to $m^{-1}$, so $m^{-1} \in \Z$ also, i.e. $m = \pm1$. Since $m > 0$, we have $m = 1$. □

**Lemma 5.5.** Let $X$ be a transitive open or closed ball (or infinite intersection of balls), and $F: X \to Y$ a definable bijection. Then there exists definable $e_0 \in RV$ such that for $x \neq x' \in X$, $\text{rv}(F(x) - F(x')) = e_0 \text{rv}(x - x')$.

**Proof.** We first show a weaker statement:

**Claim** For some definable $e_0: \Gamma \to RV$ $\text{rv}(F(x) - F(x')) = e_0(\text{val}(x - x'))\text{rv}(x - x')$ for all $x \neq x' \in X$. 

Proof. Fix $a \in X$. For $\delta \in \Gamma$, let $b_\delta = b_\delta(a)$, the closed ball around $a$ of valuation radius $\delta$. Consider those $b_\delta$ with $b_\delta \subseteq X$. As we saw in the proof of Lemma 5.1, as any $a \in X$ is generic, $b_\delta$ is transitive in $T_a$. By Lemma 3.45, \( \text{rv}(F(x) - F(a)) = f_\delta(\delta) \text{rv}(x-a) \), where \( \text{val}(x-a) = \delta \), and \( f_\delta(\delta) \) is a function of $a$ and $\delta$. But then $f_\delta$ is a function $\Gamma \to \text{RV}$, so by Lemma 3.11 it takes finitely many values $v_1, \ldots, v_n$. Let $Y_i = f_\delta^{-1}(v_i)$. $Y_i$ has a canonical code $e_i \in \Gamma^*$, consisting of the endpoints of the intervals making up $Y_i$. Using the linear ordering on $\Gamma$, each individual $e_i$ is definable from the set \{ $e_i$, $v_i$ \}, and hence from $a$; thus $v_i = f_\delta(Y_i)$ is also definable from $a$. So $f_\delta$ is definable from $(e_i, v_i)_i$. (This last argument could have been avoided by quoting elimination of imaginaries in $\text{RV} \cup \Gamma$.) However as $X$ is transitive, every definable function $X \to (\text{RV} \cup \Gamma)$ is constant, and so $f_a = f_b$ for any $a, b \in X$. Let $e_0(\delta) = f_\delta(\delta)$. \qed

We now have to show that the function $e_0$ of the Claim is constant. Using the $\text{OM}$-minimality of $\Gamma$, it suffices to show for any definable $\delta \in \text{dom}(e_0)$

1) If $e_0(\delta) = e$ then $e_0(\gamma) = e$ for sufficiently small $\gamma > \delta$.

and if $a$ is not a minimal element of $\text{dom}(e_0)$, then also:

2) If $e_0(\gamma) = e$ for sufficiently large $\gamma < \delta$, then $e_0(\delta) = e$.

To determine $e_0(\delta)$ it suffices to know $\text{rv}(F(x) - F(x'))$ and $\text{rv}(x-x')$ for one pair $x, x'$ with $\text{val}(x-x') = \delta$. Thus in 1) we may replace $X$ by a closed sub-ball $Y$ of valuation radius $\delta$, and in 2) by any closed sub-ball $Y$ of $X$ of valuation radius $\leq \delta$. Since such closed balls $Y$ are transitive (over their code), we may assume $X$ is a closed ball.

Fix $a \in X$. Pick a generic $c$ (over $a$) with $\text{rv}(c) = e$.

To prove 1), note that type of such $c$ is generic in an open ball, whereas the elements of $X$ are generic in a closed ball; these generic types are orthogonal by Lemma 3.19, so $X$ remains transitive in $T_a$. Thus we may assume (by passing to $T_a$) that $c$ is definable.

Let $q_a$ be the generic type of the closed ball \{ $x : \text{val}(a-x) \geq \delta$ \}. For $x \models q_a$, let $v_0 = \text{val}(F(a) - F(x) - c(a-x)) - \text{val}(c)$.

By the definition of $e$, $\text{val}(F(a) - F(x) - c(a-x)) \geq \text{val}(F(a) - F(x))$, so we have

\begin{align*}
(1) \quad v_0 + \text{val}(c) = \text{val}(F(a) - F(x) - c(a-x)) &> \text{val}(F(a) - F(x)) = \text{val}(c(a-x)) = \delta + \text{val}(c) \\
\text{If } \delta < \gamma < v_0, \text{ find } x, x' \models q_a \text{ with } \text{val}(x-x') = \gamma. \text{ Then } \text{val}(F(x) - F(x') - c(x-x')) &> v_0 + \text{val}_v(e) \geq \gamma + \text{val}_v(e) = \text{val}(c(x-x')), \text{ so } \text{rv}(F(x) - F(x')) = \text{rv}(c(x-x')) \text{ showing that } e_0(\gamma) = \text{rv}(c) = e. \text{ This proves 1).}
\end{align*}

For 2), let $Q_0 = \{ \gamma : \gamma < \delta \}$, $Q_0^{\text{def}}$ the set of definable elements of $Q_0$, and $Q = \{ \gamma \in Q_0 : (\forall y \in Q_0^{\text{def}})(\gamma > y) \}$. So $Q$ is a complete type of elements of $\Gamma$. For $\gamma \in Q$, according to Lemma 3.17, the formula $\text{val}(x-a) = \gamma$ generates a complete type $q_{\gamma,a}(x)$. By Lemma 3.47, $X$ is transitive over $\gamma$, so the formula $x \in X$ generates a complete $T_{\gamma}$-type. Thus by transitivity a complete $T_{\gamma}$-type $q_{\gamma}(x, x')$ is generated by: $x, x' \in X, \text{val}(x-x') = \gamma$; namely $(a, b) \models q_{\gamma,a}$.

For some definable $v_0$, for $(a, x) \models q_\gamma$ we have, as in 1):

\begin{align*}
(2) \quad \text{val}(F(a) - F(x) - c(a-x)) &> v_0(\gamma) + \text{val}(c) > \gamma + \text{val}(c)
\end{align*}

If we show that $v_0(\gamma) > \delta$ we can finish as in 1).

Now $v_0(\gamma) = m_0 + \gamma_0$ for some definable $\gamma_0 \in \Gamma$, and some rational $m$. Letting $\gamma \to \delta$ in (2) gives $m_0 + \gamma_0 \geq \delta$. If $m < 0$ then $v_0(\gamma) = m_0 + \gamma_0 > m\delta + \gamma_0 \geq \delta$ so we are done; hence we may take $m \geq 0$.

By Lemma 3.47 $\text{RV}(\theta) > \text{RV}(\eta)$; by Lemma 3.20, when $x \models q_{\gamma,a}$, $\text{RV}(\leq a, \eta)$ is generated over $\text{RV}(\leq a, \eta)$ by $\text{rv}(a-x)$.

In particular on $q_{\gamma,a}$, $x \to \text{rv}(F(a) - F(x) - c(a-x))$ is a function of $\text{rv}(a-x)$. This function lifts $v_0$ to a function on $\text{RV}$; hence by Lemma 3.26, $m \in \mathbb{Z}$. (This, and $m \geq 0$, are
simplifications rather than essential points.) We have:
\[ \text{val}((F(a) - F(x) - c(a - x))(a - x)^{-m}) = \gamma_0 \]

By Lemma 3.47, \((\text{RV} \cup \Gamma)(< a>) = (\text{RV} \cup \Gamma)(< \emptyset>)\). By Lemma 3.17, then \(\text{val}_v^{-1}(\gamma_0) \cap \text{dcl}(a, x) = \text{val}_v^{-1}(\gamma_0) \cap \text{dcl}(a)\). Thus \(\text{val}_v^{-1}(\gamma_0) \cap \text{dcl}(a, x) = \text{val}_v^{-1}(\gamma_0) \cap \text{dcl}(\emptyset)\). So \(\text{rv}((F(a) - F(x) - c(a - x))(a - x)^{-m}) \in \text{dcl}(\emptyset)\); i.e.
\[ \text{rv}((F(a) - F(x) - c(a - x))(a - x)^{-m}) = e_1 \]
for some definable \(e_1\). As in 1) we may assume there exists a definable \(c_1\) with \(\text{rv}(c_1) = e_1\). Thus for \((a, x) \models q_\gamma\),

(3) \(\text{val}((F(a) - F(x) - c(a - x) - c_1(a - x)^m)) > \text{val}(F(a) - F(x) - c(a - x)) = \nu_0(\gamma) + \text{val}(c)\)

Let \(x' \models q_\gamma,\) be generic over \(\{\gamma, a, x\}\), so in particular \(\text{val}(x - x') = \text{val}(x - a) = \text{val}(a - x') = \gamma\). We have
\[ \text{val}((F(a) - F(x') - c(a - x') - c_1(a - x')^m)) > \text{val}(F(a) - F(x) - c(a - x)) = \nu_0(\gamma) + \text{val}(c) \]

Subtracting from (3) we obtain:
(4) \(\text{val}((F(x') - F(x) - c(x - x') - c_1[(a - x)^m] - (a - x')^m])) > \nu_0(\gamma) + \text{val}(c) = \text{val}(c_1(a - x')^m)\)

But since \((x, x') \models q_\gamma,\) by (3) we have
(5) \(\text{val}((F(x) - F(x') - c(x - x') - c_1(x - x')^m)) > \nu_0(\gamma) + \text{val}(c) = \text{val}(c_1(x - x')^m)\)

Comparing (4), (5) (and subtracting \(\text{val}(c_1)\)) we see that
\[ \text{val}((a - x)^m - (a - x')^m - (x - x')^m) > \text{val}((x - x')^m) = \text{val}((a - x)^m) = \text{val}(a - x)^m\]
Let \(u = (a - x')/(x' - x);\) then \((a - x)/(x' - x) = u + 1\), \(\text{val}(u) = 0 = \text{val}(u + 1)\), and \(\text{val}((u + 1)^m - u^m - 1) > 0\). If \(U = \text{res}(u)\) we get \((U + 1)^m = U^m + 1\). Since the residue characteristic is 0 this forces \(m = 1\). (Note that \(U\) is generic.) So \(\nu_0(\gamma) = \gamma + \gamma_0\).

From (2), \(\gamma + \gamma_0 + \text{val}(c) > \gamma + \text{val}(c),\) or \(\gamma_0 > 0\). But \(\delta - \gamma_0 \in Q_{0}^{\text{dcl}},\) so since \(\gamma \in Q\) we have \(\gamma > \delta - \gamma_0,\) or \(\nu_0(\gamma) = \gamma + \gamma_0 > \delta\). As noted below (2) this proves the lemma.

\[ \square \]

Remark 5.6. In \(ACVF(p, p)\), the Claim of Lemma 5.5 remains true, but it is possible for \(e_0\) to take more than one value; consider \(x - cx^p\) on a closed ball of valuative radius 0, where \(\text{val}(c) < 0\).

Lemma 5.7. Let \(X\) be a transitive open ball, and let \(F : X \to X\) be a definable bijection. Then \(\text{rv}(F(x) - F(y)) = \text{rv}(x - y)\) for all \(x \neq y \in X\).

Proof. This follows from the second assertion in Lemma 3.45, and from Lemma 5.5. \[ \square \]

At this point, Lemma 5.1 may be improved.

Definition 5.8. Call a function \(G\) on an open ball nice if for some \(e_0,\) for all \(x \neq x' \in \text{pr}X,\)
\[ \text{rv}(G(x) - G(x')) = e_0\text{rv}(x - x').\]

Proposition 5.9. Let \(X, Y\) be definable subsets of \(VF,\) and let \(F : X \to Y\) be a definable bijection. Then there exists a partition of \(X\) to finitely many definable classes, such that on any open ball \(b\) contained in one of the classes, \(F(b)\) is an open ball, and \(F|b\) is nice.

Proof. The proof of Proposition 5.1 goes through verbatim, only quoting Lemma 5.5 along with Lemma 3.46. \[ \square \]
A definable translate of a ball $rv^{-1}(\alpha)$ will be called a **basic 1-cell**. Thus Corollary 4.3 states that every fiber of $\rho$ is a basic 1-cell. By a **basic 2-cell** we mean a set of the form:

$$X = \{(x, y) : x \in prX, rv(y - G(x)) = \alpha\}$$

where $prX$ is a basic 1-cell, and $G$ is nice.

**Corollary 5.10.** Let $X \subseteq VF^2$ be definable. Then there exists a definable $\rho : X \to RV^*$ such that every fiber is a basic 2-cell.

**Proof.** Let $X(a) = \{(a, y) \in X\}$. By Corollary 4.3 there exist an $a$-definable $\rho_a : X(a) \to RV^*$ and functions $c, c'$ such that every fiber $\rho_a^{-1}(\alpha)$ is a basic 1-cell $rv^{-1}(c'(a, \alpha)) + c(a, \alpha)$. By Lemma 2.3 we can glue these together to a function $\rho_1 : X \to RV^*$ with $\rho_1(y) = \rho_1(a, y)$. Let $p_2(x, y) = (p_1(x, y), c'(x, \rho(x, y)))$. Then any fiber $D$ of $\rho_2$ has the form $\{(x, y) : x \in pr_1 D, rv(y - G_D(x)) = \alpha\}$ where $G_D(x) = c(x, \alpha)$, $\alpha$ depending on the fiber $D$. Combining $p_2$ with a function whose fibers yield a partition as in Proposition 5.9, we may assume $G$ takes open balls to open balls (cf. Remark 5.2). Now apply Corollary 4.3 to $prX$ to obtain a map $\rho' : prX \to RV^*$ with nice fibers. \qed

### 5.3. Limits and continuity

We now assume $T$ is a $C$-minimal theory of valued fields, satisfying Assumption 3.4 (1).

Let $V$ be a $VF$-variety. By “almost all $a$” we will mean: all $a$ away from a set of smaller $VF$-dimension.

**Lemma 5.11.** Let $g$ be a definable function on a ball around 0. Then either $\text{val}(g(x)) \to -\infty$ as $\text{val}(x) \to \infty$, or there exists a unique $b \in VF$ such that $b = \lim_{x \to 0, x \neq 0} g(x)$, i.e.

$$(\forall \epsilon \in \Gamma)(\exists \delta \in \Gamma)(0 \neq x \& \text{val}(x) > \delta \implies \text{val}(g(x) - b) > \epsilon)$$

**Proof.** Let $p$ be the generic type of an element of large valuation; so $A \models pA$ iff $\text{val}(x) > \Gamma(A)$, and let $q = \text{tp}(A(c)/A)$ where $A \models pA$. By Remark 3.5, $q$ coincides with the generic type of $P$ over $A$ where $P$ is a closed ball, an open ball, or an infinite intersection of balls, or $P = VF$. The last case means that $\text{val}(g(x)) \to -\infty$. The existence of $g$ shows that $p, q$ are non-orthogonal, so it follows from Lemma 3.19 that the first case is impossible.

We begin by reducing to the case where $P$ is centered. Assume therefore that $P$ is transitive. For $b \in P$, let $q_b = \text{tp}(g(c')/A(b))$ where $c' \models pA(b)$. If $q_b$ includes a proper $b$-definable sub-ball $P_b$ of $P$, or a finite union of such balls, we may take them all to have the same radius $a(b)$; so $a(b)$ is $b$-definable. By Lemma 3.47, $\alpha$ is constant. If as $b$ varies there are only finitely many ball $P_b$, then $P$ is after all centered. If not, then there are two disjoint $P_b, P_b'$; but this is absurd since if $c'' \models pA(b, b')$ then $g(c'') \in P_b \cap P_{b'}$. Thus $q_b$ cannot include a proper sub-ball $P_b$ of $P$; so $q_b$ is just the generic type of $P$, over $A(b)$. Moving from $A$ to $A(b)$ we may thus assume that $P$ is centered.

So $P$ is a centered open or infinitely-definable ball; therefore there is a proper definable sub-ball $b$. If $y \notin b$, write $\text{val}(b - y)$ for the constant value of $\text{val}(c - y)$, $c \in b$. By the definition of a definable type of $P$, $\text{val}(b - g(c)) \notin \Gamma(A)$. Now $\text{val}(b - g(c)) \in \Gamma(A(c)) = \Gamma(A) \oplus \text{val}(c)$ (by (2) of the definition of $V$-minimality), and $\text{val}(c) > \Gamma(A)$; it follows that $\text{val}(b - g(c)) < \Gamma(A)$ or $\text{val}(b - g(c)) > \Gamma(A)$. The first case is again the case of $P = VF$, while the second implies that $P$ is an infinite intersection of balls $P_i$, whose radius is not bounded by any element of $\Gamma(A)$. In other words, $P = \{b\}$. Unwinding the definitions shows that $b = \lim_{x \to 0, x \neq 0} g(x)$.

**Remark** In reality, the transitive case considered in the proof above cannot occur.

By an (open, closed) polydisc, we mean a product of (open, closed) balls. Let $B$ be a closed polydisc. Let $M \models T$. Let $b \in B(M), a \in B(\text{acl}(\emptyset))$. Write $b \to a$ if for any definable $\gamma \in \Gamma$,...
and each coordinate \(i\), \(\text{val}(b_i - a_i) > \gamma\). Let \(p_0\) be the type of elements of \(\Gamma\) greater than any given definable element. Then Lemma 5.11 can also be stated thus: given a definable \(g\) on a ball \(B_0\) around 0 into \(B\), there exists \(b \in \text{acl}(\emptyset)\) such that if \(\text{val}(t) \models p_0\), then \((t, g(t)) \to (0, b)\).

Stated this way, the lemma generalizes to functions defined on a finite cover of \(B_0\):

**Lemma 5.12.** Let \(B_0\) be a ball around 0, and \(B\) a closed polydisc, both 0-definable. Let \(t \in B_0\) have \(\text{val}(t) \models p_0\), and let \(a \in \text{acl}(t)\), \(a \in B\). Then there exists \(b \in B\), \(b \in \text{acl}(\emptyset)\) with \((t, a) \to (0, b)\).

**Proof.** The proof of Lemma 5.11 goes through. \(\square\)

The following is an analogue of a result of Macintyre’s for the \(p\)-adics. By the boundary of a set \(X\), we mean the closure minus the interior of \(X\).

**Lemma 5.13.**

1. Any definable \(X \subseteq \text{VF}^n\) of dimension \(n\) contains an open polydisc.
2. Any definable function \(\text{VF}^n \to \text{RV} \cup \Gamma\) is constant on some open polydisc.
3. The boundary of any definable \(X \subseteq \text{VF}^n\) has dimension < \(n\).

**Proof.** Given (1), (3) follows since the boundary is definable; so it suffices to prove (1,2). For a given \(n\), (2) follows from (1): by Lemma 3.56, the fibers of the function cannot all have dimension \(< n\).

For \(n = 1\), (1) is immediate from \(C\)-minimality. Assume (1,2) true for \(n\) and let \(X \subseteq \text{VF} \times \text{VF}^n\) be a definable set of dimension \(n+1\). For any \(a \in \text{VF}^n\) such that \(X_a = \{b : (a, b) \in X\}\) contains an open ball, let \(\gamma(a)\) be the infimum of all \(\gamma\) such that \(X_a\) contains an open \(\gamma\)-ball. By (2) for \(n\), \(\gamma\) takes a constant value \(\gamma_0\) on some polydisc \(U\); pick \(\gamma_1 > \gamma_0\). Let \(X' = \{(u, z) \in X : u \in U, (\forall z')(\text{val}(z - z') > \gamma_0 \implies (u, z') \in X)\}. Then \(\text{dim}(X') = n + 1\).

Now consider the projection \((u, z) \mapsto z\). For some \(c \in \text{VF}\), the fiber \(X'_c = \{u : (u, c) \in X'\}\) must have dimension \(n\). By induction, \(X'_c\) contains a polydisc \(V\). Now clearly \(V \times B^{n+1}_\gamma(c) \subseteq X\). \(\square\)

If \(x = (x_1, \ldots, x_n), x' = (x'_1, \ldots, x'_n)\), write \(\text{val}(x-x') = \text{min} \text{val}(x_i-x'_i)\). Say a function \(F\) is \(\delta\)-Lipschitz at \(x\) if whenever \(\text{val}(x-x')\) is sufficiently large, \(\text{val}(F(x) - F(x')) > \delta + \text{val}(x-x')\). Say \(F\) is locally Lipschitz on \(X\) if for any \(x \in X\), for some \(\delta \in \Gamma\), \(F\) is \(\delta\)-Lipschitz at \(x\).

**Lemma 5.14.** Let \(F : X \subseteq \text{VF}^n \to \text{VF}\) be a definable function. Then \(F\) is continuous away from a subset \(X'\) of dimension < \(n\). Moreover \(F\) is locally Lipschitz on \(X \setminus X'\).

**Proof.** Let \(X'\) be the (definable) set of points \(x\) where \(F\) is not Lipschitz. We must show that \(X'\) has dimension \(< n\) (in this case, by Lemma 5.13, the closure of \(X'\) has dimension \(< n\) too.) Suppose otherwise. For \(n = 1\) the lemma follows from Lemmas 5.1 and 5.4. Let \(\pi_i : X' \subseteq \text{VF}^n \to \text{VF}^{n-1}\) be the projection along the \(i\)th coordinate axis. Let \(Y\) be the set of \(b \in \text{VF}^{n-1}\) such that \(\pi_i^{-1}(b)\) is infinite, or equivalently contains a ball; it is a definable set. For \(b \in Y\), let \(D_i(b) = \{x \in \pi_i^{-1}(b) : (3\delta \in \Gamma)(F|\pi_i^{-1}(b) \text{ is } \delta\text{-Lipschitz near } x)\}\)

By the case \(n = 1\), \(\pi_i^{-1}(b) \setminus D_i(b)\) is finite. Thus if \(D_i = \bigcup_{b \in Y} D_i(b)\), then \(\pi_i\) has finite fibers on \(X \setminus D_i\), so \(\text{dim}(X \setminus D_i) < n\). Let \(X' = \bigcap_i D_i\), and for \(x \in X'\) let \(\delta(x)\) be the infimum of all such Lipschitz constants \(\delta\) (for all \(n\) projections.) By Lemma 5.13, \(\delta\) is constant on some open polydisc \(U \subseteq X'\). Let \(\delta' > \delta\) be greater than this constant value. Then at any \(x \in U\), the restriction of \(F\) to a line parallel to an axis is \(\delta'\)-Lipschitz. It follows immediately (using the ultrametric inequality) that \(F\) is \(\delta'\)-Lipschitz on \(U\); but this contradicts the definition of \(X'\). \(\square\)
Remark 5.15. Via Assumption 3.4 (1), we used the existence of $p$-torsion points in the kernel of $RV \to \Gamma$ for each $p$. In $ACVF(p, p)$ this fails; one can still show that $F$ is locally logarithmically Lipschitz, i.e., for some rational $\alpha > 0$, for any $x \in X \setminus X'$, for sufficiently close $x'$, $\text{val}(F(x) - F(x')) > \alpha \text{val}(x - x')$.

5.4. Differentiation in $VF$. Let $F : VF^n \to VF$ be a definable function, defined on a neighborhood of $a \in VF^n$. We say that $F$ is differentiable at $a$ if there exists a linear map $L : VF^n \to VF$ such that for any $\gamma \in \Gamma$, for large enough $\delta \in \Gamma$, if $\text{val}(x_i) > \delta$ for each $i, x = (x_1, \ldots, x_n)$, then $\text{val}(F(a + x) - F(a) - Lx) > \delta + \gamma$. If such an $L$ exists it is unique, and we denote it $dF_a$.

Lemma 5.16. Let $F : X \subseteq VF^n \to VF^m$ be a definable function. Then each partial derivative is defined at almost every $a \in X$.

Proof. We may assume $n = m = 1$. Let $g(x) = (F(a + x) - F(a))/x$. By Lemma 5.4, for almost every $a$, for some $\delta \in \Gamma$, for all $x$ with $\text{val}(x)$ sufficiently large, $\text{val}(F(a + x) - F(a)) = \delta + \text{val}(x)$; so $\text{val}(g(x))$ is bounded. By Lemma 5.11, and Proposition 5.1, $g(x)$ approaches a limit $b \in VF$ as $x \to 0$ (with $x \neq 0$); the lemma follows. □

Corollary 5.17. Let $F : VF^n \to VF$ be a definable function. Then $F$ is continuously differentiable away from a subset of dimension $< n$.

Proof. $F$ has partial derivatives almost everywhere, and these are continuous almost everywhere, so the usual proof works. □

Lemma 5.18. Let $X \subseteq VF^n \times RV^m$ be definable, $pr : X \to VF^n$ the projection. Then for almost every $p \in VF^n$, there exists an open neighborhood $U$ of $p$ and $H \subseteq RV^m$ such that $pr^{-1}(U) = U \times H$. If $h : X \to VF$, then for almost all $x \in X$, $h$ is differentiable with respect to each $VF$-coordinate.

Proof. For $x \in VF^n$, let $H(x) = \{h \in RV^m : (x, h) \in X\}$. By Corollary 3.24, Lemma 2.8, there exists $H' \subseteq RV^m \times RV^l \times \Gamma^k$ such that for any $x \in VF^n$, there exists a unique $y = f(x) \in RV^l \times \Gamma^k$ with $H(x) = H'(y)$. By Lemma 5.13, $f$ is locally constant almost everywhere. Thus for almost all $x$, for some neighborhood $U$ of $x$, for all $x' \in U$, $H(x) = H(x')$; so $pr^{-1}U = U \times H(x)$. The last assertion is immediate. □

This allows the definition of partial derivatives of a definable map $F : X \to VF$ (almost everywhere); we just take them with respect to the $VF$-coordinates, ignoring the $RV$-coordinates.

Given $h : X \to VF^n, h' : X' \to VF^n$ with $RV$-fibers, and a definable map $F : X \to X'$, we define the partials of $F$ to be those of $h' \circ F$. Then the differential $dF_x$ exists at almost every point $x \in X$ by Corollary 5.17, and we denote the determinant by $\operatorname{Jcb}$, and refer to it as usual as the Jacobian.

Definition 5.19. Let $X, X' \in VF[n,-]$ and let $F : X \to X'$ be a definable bijection. $F$ is measure preserving if $\text{rvJcb}(x) = 1$ for almost all $x \in X$. $VF_{vol}[n,-]$ is the subcategory of $VF[n,-]$ with the same objects, and whose morphisms are the measure preserving morphisms of $VF[n,-]$.

Let $VF_{vol}$ be the category whose objects are those of $VF[n,-]$, and whose morphisms $X \to Y$ are the essential bijections $f : X \to Y$ that are measure preserving.
5.5. **Differentiation and Jacobians in RV.** Let $X, Y$ be definable sets, together with finite-to-one definable maps $f_X : X \to RV^n, f_Y : Y \to RV^n$. Here $X, Y$ can be subsets of RV* or of $RV^* \times VF^*$, etc.; the notion of Jacobian will not depend on the particular realization of $X, Y$.

Let $h : X \to Y$ be a definable map.

The notion of Jacobian will depend not only on $h, X, Y$ but also on $f_X, f_Y$; to emphasize this we will write $h : (X, f_X) \to (Y, f_Y)$.

We first define smoothness. When $A = f_X(X), B = f_Y(Y)$ are definable subsets of $k^n$, we say $h, X, Y$ are smooth if $A, B$ are Zariski open, $\{(f_X(x), f_Y(h(x))) : x \in X \} \cap (A \times B) = Z$ for some nonsingular Zariski closed set $Z \subset A \times B$, and the differentials of the projections to $A$ and to $B$ are isomorphisms at any point $z \in Z$. In this case, composing the inverse of one of these differentials with the other, we obtain a linear isomorphism $T_a(A) \to T_b(B)$ for any $a = f_X(x), b = f_Y(h(x))$; since $T_a(A) = k^n = T_b(B)$, this linear isomorphism is given by an invertible matrix, whose determinant is the Jacobian $J$.

In general, to define smoothness of $X, Y$ at $(x, y = h(x))$, we restrict to the cosets of $(k^*)^n$ containing $x$ and $y$, translate multiplicatively by $x$ and $y$ respectively, and pose the same condition.

Any $X, Y, h$ are smooth outside of a set $E$ where $E \cap C$ has dimension $< n$ for each coset $C$ of $(k^*)^n$. Equivalently (by Lemma 3.64) $E$ has RV-dimension $< n$.

Assume now that $X, Y, h$ are smooth. Define

$$J_{cbRV}(h)(q) = \Pi(f_X(q))^{-1}\Pi(f_Y(q'))J(1, 1) \in RV$$

where $\Pi(c_1, \ldots, c_n) = c_1 \cdots c_n$.

At times it is preferable not to use a different translation at each point of a coset of $(k^*)^n$.

The Jacobian $J_{cbRV}(h)$ of $h$ at $q \in X$ can also be defined as follows. Let $q' = h(q), \gamma = val_{rv}(q), \gamma' = val_{rv}(q') \in \Gamma^n$. Pick any $c, d \in RV^n$ with $val_{rv}(c) = \gamma, val_{rv}(d) = \gamma'$ (one can take $c = f_X(q), d = f_Y(q')$). Let

$$W(\gamma, \gamma') = \{a : f_X(a) \in val_{rv}^{-1}(\gamma), f_Y(h(a)) \in val_{rv}^{-1}(\gamma')\}$$

$$H' = \{(c^{-1}f_X(a), d^{-1}f_Y(h(a))) : a \in W\}$$

Since $f_X, f_Y$ are finite-to-one, $H' \subset (k^*)^{2n}$ both projections of $H'$ to $k^*$ are finite-to-one, and $H'$ is nonsingular by the smoothness of $(X, Y; h)$. We can thus define the Jacobian $J'$ of $H'$ at any point. We have:

$$J_{cbRV}(h)(q) = \Pi(c)^{-1}\Pi(d)J'(qc^{-1}, q'd^{-1}) \in RV$$

We also define $J_{cb}(h)(q) = \sum \gamma' - \sum \gamma \in \Gamma$ (writing $\Gamma$ additively). Note that this depends only on the value of $h$ at $q$. We have:

$$val_{rv}J_{cbRV}(h)(q) = J_{cb}(h)(q)$$

**Example 5.20. Jacobian of maps on $\Gamma$.** If $\tilde{X}, \tilde{Y} \subset \Gamma^n$, we saw that a definable map $\tilde{f} : \tilde{X} \to \tilde{Y}$ lifts to RV iff it is piecewise given by an element of $GL_n(\mathbb{Z})$ composed with a translation. Assume $\tilde{f}$ is given by a matrix $M \in GL_n(\mathbb{Z})$, let $X = val_{rv}^{-1}(\tilde{X}), Y = val_{rv}^{-1}(\tilde{Y})$, and let $f : X \to Y$ be given by the same matrix, but multiplicatively. Then $X, Y, f$ are smooth, and

$$J(f)(x) = \Pi(y)\Pi(x)^{-1} \det M$$

where $y = f(x)$, and $\det(M) = \pm 1$. 

5.5.1. Alternative: \(\Gamma\)-weighted polynomials. We have seen that the geometry on \(\text{val}_{\nu}^{-1}(\gamma)\) (\(\gamma \in \Gamma^n\)) translates to the geometry on \((k^*)^n\), but this is true for the general notions and not for specific varieties; a definable subset of \(C(\gamma) = \text{val}^{-1}(\gamma)\) does not correspond canonically to any definable subset of \(\text{val}^{-1}(0)\). An invariant approach is therefore useful. Let \(\Gamma_0 = \Gamma(< \emptyset >)\), \(X = (X_1, \ldots, X_n)\) be variables, \(\gamma = (\gamma_1, \ldots, \gamma_n) \in \Gamma_0^n\), and let \(\nu = (\nu(1), \ldots, \nu(n)) \in \mathbb{N}^n\) denote a multi-index. By a \(\gamma\)-weighted monomial we mean an expression \(a_{\nu}X^\nu\) with \(a_{\nu}\) a definable element of \(\text{RV}\), such that \(\text{val}_{\nu}(a_{\nu}) + \sum \nu(i)\gamma_i = 0 \in \Gamma\). Let \(\text{Mon}(\gamma, \nu)\) be the set of \(\gamma\)-weighted monomials of exponent \(\nu\), together with 0. Then \(\text{Mon}(\gamma, \nu) \setminus \{0\}\) is a copy of \(\text{val}_{\nu}^{-1}(-a_{\nu}) + \sum \nu(i)\gamma_i\); so \(\text{Mon}(\gamma, \nu)\) is a one-dimensional \(k\)-space. In particular addition is defined in \(\text{Mon}(\gamma, \nu)\). We also have a natural multiplication \(\text{Mon}(\gamma, \nu) \times \text{Mon}(\gamma', \nu') \rightarrow \text{Mon}(\gamma, \nu + \nu')\). Let \(R[X; \gamma] = \oplus_{\nu \in \mathbb{N}^n} \text{Mon}(\gamma, \nu)\). This is a finitely generates graded \(k\)-algebra. It may be viewed as an affine coordinate ring of \(C[\gamma]\); but the ring of the product \(C[\gamma, \gamma']\) is \(R[X, X'; (\gamma, \gamma')]\), in general a bigger ring than \(R[X, \gamma] \otimes_k R[X', \gamma']\). Nevertheless, a Zariski closed subset of \(C(\gamma)\) corresponds to a radical ideal of \(R[X'; \gamma]\). In this way notions such as smoothness may be attributed to closed or constructible subsets of any \(C(\gamma)\) in an invariant way.

**Definition 5.21.** Let \(X, Y \in \text{Ob} \text{RV}[n, -]\) and let \(h : X \rightarrow Y\) be a definable bijection. \(h\) is measure preserving if \(\text{Jcb}_{\Gamma} h(x) = 0\) for all \(x \in X\), and \(\text{Jcb}_{\text{VR}} h(x) = 1\) for all \(x \in X\) away from a set of \(\text{RV}\)-dimension < \(n\). If only the first condition holds, we say \(h\) is \(\Gamma\)-measure preserving.

For \(X, Y \in \text{RV}[\leq n, -]\), we say \(h : X \rightarrow Y\) is measure preserving if this is true of the \(\text{RV}[n]\)-component of \(h\).

\(\text{RV}_{\text{vol}}[n, -]\) (respectively \(\text{RV}_{\text{vol}}[n, -]_{\Gamma}\)) is the subcategory of \(\text{RV}[n, -]\) with the same objects, and whose morphisms are the measure preserving (respectively \(\Gamma\)-measure preserving) definable bijections.

\(\text{RV}_{\text{vol}}[\leq n, -] = \oplus_{k < n} \text{RV}_{\text{vol}}[k, -] \oplus \text{RV}_{\text{vol}}[n, -]\).

Note that when \(X, Y \in \text{Ob} \text{RV}[n, -]\), a bijection \(h : X \rightarrow Y\) is \(\Gamma\)-measure preserving iff it leaves invariant the sets \(S_\gamma = \{(a_1, \ldots, a_n) : \sum_{i=1}^{n} \text{val}_{\nu}(a_i) = \gamma\}\).

5.6. Comparing the derivatives. Consider a definable function \(F : \text{VF} \rightarrow \text{VF}\) lying above \(f : \text{RV} \rightarrow \text{RV}\), i.e. \(\text{rv}F = f_{\text{rv}}\). The fibers of the map \(\text{rv} : \text{VF} \rightarrow \text{RV}\) above \(k\), for instance, are open balls of valuate radius 0, whereas the derivative is defined on the scale of balls of radius \(r\) for \(r \rightarrow +\infty\). Thus the comparison between the derivatives of \(F\) and \(f\) is not tautological. Nevertheless one obtains the expected relation almost everywhere.

While this case of the affine line would suffice (using the usual technique of partial derivatives), it is easier to place oneself in the more general context of curves. More precisely we consider definable sets \(C\) together with finite-to-one maps \(f : C \rightarrow \text{RV}\). Let \(\text{LC}\) and \(\rho : \text{LC} \rightarrow C\) be as above.

In the following lemma, \(H', h'\) denote respectively the VF, \(\text{RV}\)-derivatives of functions \(H, h\) defined on objects of \(\text{VF}[1], \text{RV}[1]\) respectively.

**Proposition 5.22.** Let \(C_i \subseteq \text{RV}^*\) be definable sets, \(f_i : C_i \rightarrow \text{RV}\) finite-to-one definable maps \((i = 1, 2)\). Let \(h : C_1 \rightarrow C_2\) be a definable bijection, and let \(H : \text{LC}_1 \rightarrow \text{LC}_2\) be a lifting of \(h\), i.e. \(\rho H = h\rho\). Then

1. For all but finitely many \(c \in C_1\), \(h\) is differentiable at \(c\), \(H\) is differentiable at any \(x \in \text{LC}_1\), and \(\text{rv} H'(x) = h'(\text{rv}(x))\).

2. For all \(c \in C_1\), \(H\) is differentiable at a generic \(x \in \text{LC}_1\), and \(\text{val} H'(x) = (\text{val}_{\nu} h')(x) = \text{val}(f_2(h(x))) = \text{val}(f_1(x))\).
Proof. (1) Let $Z'$ be the set of $x \in Lc_1$ such that $H$ is not differentiable at $x$ (a finite set) or that $rv(H'(x)) \neq h'(rv(x))$. We have to show that $\rho(Z') \subseteq C$ is finite, or equivalently that $f_1 \circ \rho(Z')$ is finite. Otherwise there exists $c \in \rho(Z')$ with $c \notin acl(A)$. By Lemma 3.20, the formula $rv(x) = f_1(c)$ generates a complete type $q$ over $A(c)$; it defines a transitive open ball $b_c$ over $A(c)$. Since $\rho \circ H = \rho \circ h$, we have $H(c, y) = (c, H(c, y))$ for some $A(c)$-definable bijection $H_c$ of $b_c$. By Lemma 5.5, for some $c_0 \in RV$, $rv(H(u) - H(v)) = e_0 rv(u - v)$ for all $u, v \in b_c$; so $rv((H(u) - H(v))/(u - v)) = e_0$. Since $H$ is differentiable almost everywhere on $b_c$, (Lemma 5.17) and $b_c$ is transitive, it is differentiable at every point. Clearly $rvH'(u) = e_0$, contradicting the definition of $Z'$. (2) follows from Lemma 5.4.

Corollary 5.23. Let $X \in Ob\ RV[n], \ F : LX \rightarrow VF^n$ a definable function, $f : LX \rightarrow RV^n$ a definable function. Assume $rvF(x) = f(rv(x))$. Then Proposition 5.22 applies for each partial derivative of $F$. In particular,
- For all $c \in X$ away from a set of smaller dimension, for all $x \in Lc, \ F$ is differentiable at $x$, $f$ is differentiable at $c$, and $rvJcb(F)(x) = Jcb_{rv}(f)(x)$.
- For all $c \in X$, for generic $x \in Lc, \ F$ is differentiable at $x$, and $valJcb(F)(x) = (Jcb_{rf}(f)(x))$.

Corollary 5.24. Let $X, Y \in Ob\ RV[\leq n], \ f \in Mor_{RV[\leq n]}(X, Y), \ F \in Mor_{VF_{\leq n}}(LX, LY)$. Assume $rvF(x) = f(rv(x))$. Then $f \in Mor_{RV_{\leq n}}(X, Y)$.

Proof. Follows from Corollary 5.23.

6. LIFTING FUNCTIONS FROM RV TO VF

Proposition 6.1. Let $T$ be an effective $V$-minimal theory. Let $X \subset RV^k$ be definable and let $\phi_1, \phi_2 : X \rightarrow RV^n$ be two definable maps with finite fibers. Then there exists a definable bijection $F : X \times _{\phi_1, rv}(VF^*)^n \rightarrow X \times _{\phi_2, rv}(VF^*)^n$, commuting with the natural projections to $X$.

Proof. Let $A = acl(\emptyset) \cap (VF \cup \Gamma)$. If $b \in acl(\emptyset) \cap RV$, then viewed as a ball $b$ has a point $a \in A$; since the valuative radius of $b$ is also in $A$, we have $b \in acl(A)$. Thus $\phi_1, \phi_2, X$ are $ACVF_A$-definable. Any $ACVF_A$-definable bijection $F$ is a fortiori $T$-definable; so the Proposition for $ACVF_A$ implies the Proposition for $T$. Moreover $ACVF_A$ is $V$-minimal and effective, since any algebraic ball of $ACVF_A$ is $T_A$-algebraic and hence has a point in $VF(A)^{\emptyset \emptyset \emptyset}$. Thus we may assume $T = ACVF_A$.

The proof will be asymmetric, concentrating on $\phi_1$. We may definably partition $X$, and prove the proposition on each piece.

Consider first the case where $\phi_1 : X \rightarrow U$ and $\phi_2 : X \rightarrow V$ are bijections to definable subsets $U, V \subseteq (k^*)^k$. Our task is to lift the bijection $f = \phi_2 \phi_1^{-1}$ to $VF^n$. A definable subset of $k^n$ (such as $\phi_1(X)$) is a disjoint union of smooth varieties. We thus consider a definable bijection $f : U \rightarrow V$ between $k$ varieties $U \subseteq k^n$ and $V \subseteq k^n$. Induction on $\dim(U)$ will allow us to remove a subset of $U$ of smaller dimension. Hence we may assume $U$ is smooth, cut out by $h = (h_1, \ldots, h_l), \ TU = Ker(dh), f = (f_1, \ldots, f_n)$ where $f_i$ are regular on $U$ (defined on an open subset of $k^n$), and $df$ is injective on $TU$ at each point of $U$. Thus the common kernel of $dh_1, \ldots, dh_l, df_1, \ldots, df_n$ equals 0.

It follows that at a generic point of $U$ (i.e. every point outside a proper subvariety), if $Q$ is a sufficiently generic $n \times l$ matrix of elements of $A$ (or integers), and we let $f'_i = f_i + Qh$, then the common kernel of $df'_1, \ldots, df'_n$ vanishes. Note that $f'_i(U) = f'_i|U$. Let $W$ be a smooth variety
contained in \( f(U) \) and whose complement in \( f(U) \) is a constructible set of dimension smaller than \( \dim(U) \). Replacing \( U \) by \( f^{-1}(W) \), we may assume \( f(U) \) is also a smooth variety.

Let \( \hat{U} = \text{res}^{-1}(U) \). Lift each \( f_i' \) to a polynomial \( F_i \) over \( 0 \), with definable coefficients. This is possible by effectiveness of \( \text{ACVF}_A \). Obtain a regular map \( F \), whose Jacobian is invertible at points of \( \hat{U} \). We have \( \text{res} \circ F = f \circ \text{res} \). Since \( f \) is 1-1 on \( U \), the invertibility of \( dF \) implies that \( F \) is 1-1 on \( \hat{U} \). Moreover, by Hensel's lemma, \( F : \text{rv}^{-1}(U) \rightarrow \text{rv}^{-1}(W) \) is bijective.

Next consider the case where in place of a bijection \( f : U \rightarrow V \) we have a finite-to-finite correspondence \( \hat{f} \subset U \times V \) (where \( U = \phi_1(X), V = \phi_2(X) \)), \( \hat{f} = \{ \langle \phi_1(x), \phi_2(x) \rangle : x \in X \} \). We may take \( \hat{f} \subset U \times V \) to be a subvariety, unramified and quasi-finite over \( U \) and over \( V \); and we can take \( U, V \) to be smooth varieties. As before we can lift \( \hat{f} \) to a correspondence \( \hat{F} \subset U \times V \), such that \( \hat{F} \cap \text{rv}^{-1}(u) \times \text{rv}^{-1}(v) \) is a bijection \( \text{rv}^{-1}(u) \rightarrow \text{rv}^{-1}(v) \) whenever \((u, v) \in \hat{F} \). It follows that a bijection \( X \times \phi_{1,rv}(VF^X)^n \rightarrow X \times \phi_{2,rv}(VF^X)^n \) is given by: \((x, y) \mapsto (x, y')\) iff \((y, y') \in F \).

If \( \phi_1 : X \rightarrow U \) and \( \phi_2 : X \rightarrow V \) are bijections to definable subsets \( U, V \), each contained in a single coset of \( (k^*)^k \), say \( U \subseteq C(\gamma), V \subseteq C(\gamma') \) for some \( \gamma, \gamma' \in \Gamma^k \) (cf. §5.5.1.) Let \( Z = (Z_1, \ldots, Z_k) \) be variables, \( R[Z; \gamma] \) be the subring of \( \text{VF}[Z] \) consisting of polynomials \( \sum a_{\nu} Z^\nu \), with \( \text{val}(a_{\nu}) + \sum_{i=1}^{r} \nu(\gamma_i) = 0 \), and \( a_{\nu} \) a definable element of \( \text{VF} \). There is a natural homomorphism \( R[Z; \gamma] \rightarrow \hat{R}[Z; \gamma] \), where \( \hat{R}[Z; \gamma] \) is the coordinate ring of \( C(\gamma) \). By effectivity, this homomorphism is surjective. The proof now proceeds in exactly the same way as above.

This proves the proposition in case \( \text{val}_r \phi_1(X) \) consists of one point.

Next assume \( \text{val}_r \phi_2 \) consists of one point, and \( \text{val}_r \phi_1(X) \) is finite. So \( \phi_1(X) \) lies in the union of finitely many cosets \( (C(a) : a \in E) \), with \( E \) finite.

For \( a \in E \), \( A(a) \) remains almost \( \text{VF}, \Gamma \)-generated; since the proposition is true for \( \phi_1^{-1}C(a) \) (definable in \( T_{A(a)} \)), then so by the one-coset case an appropriate isomorphism \( F \) exists; and the finitely many \( F \) obtained this way can then be glued together, to yield a map defined over \( A \).

The case of \( \text{val}_r \phi_1, \text{val}_r \phi_2 \) both finite is treated similarly.

This proves the existence of a lifting in case \( \text{val}_r \phi_1(X) \) is finite. Now for the general case.

Claim Let \( P \subset X \) be a complete type. Then there exists a definable \( D \subset P \subset D \subset X \), and definable functions \( \theta \) on \( \text{val}_r(\phi_1(D)) \) and \( \theta' \) on \( \text{val}_r(\phi_2(D)) \) such that for \( x \in D \), \( \theta(\text{val}_r(\phi_1(x))) = \text{val}_r(\phi_2(x)), \theta'(\text{val}_r(\phi_2(x))) = \text{val}_r(\phi_1(x)) \).

Proof. Let \( a \in P, \gamma_i = \text{val}_r(\phi_i(a)) \). Then \( \gamma_2 \) is definable over some points of \( \phi_1^{-1} \text{val}_r^{-1}(\gamma_1) \). But \( \text{val}_r^{-1}(\gamma_1) \) is a coset of \( k^* \), and \( \phi_1 \) is finite-to-one, so \( \phi_1^{-1} \text{val}_r^{-1}(\gamma_1) \) is orthogonal to \( \Gamma \). Thus \( \gamma_2 \) is algebraic over \( \gamma_1 \). Since \( \Gamma \) is linearly ordered, \( \gamma_2 \) is definable over \( \gamma_1 \); so \( \gamma_2 = \theta(\gamma_1) \) for some definable \( \theta \). Similarly \( \gamma_1 = \theta'(\gamma_2) \). Clearly \( \theta \) restricts to a bijection \( \text{val}_r \phi_1 P \rightarrow \text{val}_r \phi_2 P \), with inverse \( \theta' \). By Lemma 2.7 there exists a definable \( D \) with \( \theta \phi_1 = \phi_2, \phi_1 = \theta' \phi_2 \) on \( D \).

Now by compactness, there exist finitely many \( (D_i, \theta_i, \theta'_i) \) as in the claim with \( \bigcup D_i = X \). We may cut down the \( D_i \) successively, so we may assume the union is disjoint. But in this case the proposition reduces to the case of each individual \( D_i \), so we may assume \( X = D \). Let \( B_i = \text{val}_r \phi_i(X) \). Given \( b \in B_1 \), let \( X_b = (\text{val}_r \phi_1)^{-1}(b) \). Then by the case already considered there exists an \( A(b) \)-definable \( F_b : X_b \times \phi_1,rv \times (VF^X)^n \rightarrow X_b \times \phi_2,rv \times (VF^X)^n \). Let \( F = \cup_{b \in B_1} F_b \). By Lemma 2.3, \( F : X \times \phi_{1,rv}(VF^X)^n \rightarrow X \times \phi_{2,rv}(VF^X)^n \) is bijective. (see discussion in §2.1.1.)

We note a corollary:

**Lemma 6.2.** Let \( T \) be \( \text{VF} \)-minimal and effective, and let \( A \) be an almost \( \text{(VF}, \Gamma) \)-generated structure. Then \( A \) is effective.
Proof. By Lemma 3.29 it suffices to show \( A \) is \( rv \)-effective. Note that if \( A \subseteq \text{acl}(\emptyset) \), then \( T \) is \( rv \)-effective iff \( T_A \) is \( rv \)-effective (see proof of Lemma 3.31 (2 \( \rightarrow \) 3).) Thus it suffices to show that if \( A_0 = \text{acl}(A) \), \( a \in VF \cup \Gamma \), and \( T' = T_{A_0} \) is effective then so is \( T' \). The case \( a \in \Gamma \) is included in Corollary 3.40, so assume \( a \in VF \). Let \( P \) be the intersection of all \( A_0 \)-definable balls containing \( a \). If \( P \) is transitive over \( A_0 \), then by Lemma 3.47 we have \( RV(A_0(a)) = RV(A_0) \), so \( rv \)-effectiveness remains true trivially. Otherwise \( P \) is centered over \( A_0 \), hence has an \( A_0 \)-definable point, and by translation we may assume \( 0 \in P \), \( a \) is then a generic point of \( P \) over \( A_0 \). Let \( c \in RV(A_0(a)) \); we must show that \( rv^{-1}(c) \) is centered over \( A_0(a) \). By Lemma 3.20, if \( c \in RV(A_0(a)) \) then \( c = f(d) \) for some \( A_0 \)-definable function \( f : RV \to RV \), where \( d = rv(a) \). By Lemma 6.1 there exists an \( A_0 \)-definable function \( F : VF \to VF \) lifting \( f \). Then \( F(d) = rv^{-1}(c) \). \( \square 

6.0.1. Base change: summary. Base change from \( T \) to \( T_A \) preserves \( V \)-minimality, effectiveness and being resolved, if \( A \) is \( VF \)-generated; \( V \)-minimality and effectiveness, if \( A \) is \( RV \)-generated; \( V \)-minimality, if \( A \) is \( \Gamma \)-generated. (Lemmas 6.2, 3.39, 3.40. The resolved case follows using 3.49.) 

Though the notion of a morphism \( g : (X_1, \phi_1) \to (X_2, \phi_2) \) does not depend on \( \phi_1, \phi_2 \), recall that the \( RV \)-Jacobian of \( g \) is defined with reference to these finite-to-one maps.

Lemma 6.3. Let \( T \) be \( V \)-minimal and effective. Let \( X_i \subseteq RV^{k_i} \) be definable and let \( \phi_i : X \to RV^n \) be definable maps with finite fibers; let \( g : X_1 \to X_2 \) be a definable bijection. Assume given in addition a definable function \( \delta : X_1 \to RV \), such that:

1. \( \text{val}_v \delta(x) = Jcb_T g(x) \) for all \( x \in X_1 \).
2. \( \delta(x) = Jcb_{VXY} g(x) \) for almost all \( x \in X_1 \) (i.e. all \( x \) outside a set of dimension \( < n \).)

Then there exists a definable bijection \( G : X_1 \times_{\phi_1, rv} (VF^x)^n \to X_2 \times_{\phi_2, rv} (VF^x)^n \) such that \( \rho_2 \circ G = g \circ \rho_1 \), where \( \rho_i \) is the natural projections to the \( X_i \), and such that for any \( x \in X_1 \times_{\phi_1, rv} (VF^x)^n \), \( G \) is differentiable at \( x \), and \( rv(Jcb(G)(x)) = \delta(x) \).

Proof. We follow closely the proof of Proposition 6.1. As there, we may assume \( T = ACV F_A \), with \( A \) be an almost \( (VF, \Gamma) \)-generated substructure.

We first assume that \( \text{val}_v \phi(X_1) \) is a single point of \( \Gamma^n \). Then \( X_1 \) can be definably embedded into \( k^N \) for some \( N \), and it follows from the orthogonality of \( k \) and \( \Gamma \) that the image of \( X_1 \) in \( \Gamma \) under any definable map is finite. Thus \( \phi_2 X_2 \) is contained in finitely many cosets \( (C(a) : a \in S) \) of \( (k^*)^n \); by partitioning \( X_1 \) working in \( T_{A(a)} \), we may assume \( \phi_2 X_2 \) is contained in a single coset. (cf. Lemma 2.3.)

As in Proposition 6.1, we may assume \( \phi_1 X \subseteq k^n \), and indeed that \( \phi_1 X = U, \phi_2 X = V \) are smooth varieties. If \( \text{dim}(U) = n \), then the lift constructed in Proposition 6.1 satisfies \( rv(Jcb(G))(x) = Jcb_{VXY} g(x) \) for \( x \in X \times_{\phi_1, rv} VF^n \); thus by assumption (2), we have \( rv(Jcb(G))(x) = \delta(x) \) for almost all \( x \). The exceptional points have dimension \( < n \), and may be partitioned into smooth varieties of dimension \( < n \). Thus we are reduced to the case \( \text{dim}(U) < n \). We prove it by induction on \( \text{dim}(U) \). In this case choose any lifting \( G_0 \). We have an error term \( \epsilon(x) = rv(Jcb(G_0))(x) - \delta(x) \). Now \( A(x) \) is almost \( VF, \Gamma \)-generated, and so balls \( rv^{-1}(y) \) contain definable points; thus \( \epsilon(x) = rv E(x) \) for some definable \( E : (X \times_{\phi_1, rv} VF^n) \to VF \). Since \( U \) is a smooth subvariety of \( k^n \) of positive codimension, some regular \( h \) on \( k^n \) vanishes on \( V \), while some partial derivative (say \( h_1 \)) vanishes only on a smaller-dimensional subvariety. By induction may assume \( h_1 \) vanishes nowhere. Lift \( h \) to \( H \); so \( H \) lifts \( h_1 \). Compose \( G_0 \) with a map fixing all coordinates but the first, and multiplying the first coordinate by \( E(x) H(y)/H_1(y) \). (Here \( x = g^{-1}(y) \).) Where \( h \) vanishes, this has Jacobian \( E(x) \); so the composition has \( RV \)-Jacobian \( \delta(x) \) as required.
Now in general. For any $\gamma \in \Gamma^n$ let $X_1(\gamma) = \{x \in X_1 : \val_{\gamma} \phi_1(x) = \gamma\}$, $X_2(\gamma) = g(X_1(\gamma))$. By definition of $JcbrV$ and $Jcbr$, $JcbrV(g) X_2(\gamma) = JcbrV(g) X_2(\gamma)$ and likewise $Jcbr$. By the case already analyzed (for the sets $X_1(\gamma), X_2(\gamma)$ defined in $ACF_{\Gamma(\gamma)}$) there exists an $A(\gamma)$-definable bijection $G_\gamma : X_1(\gamma) \times \phi_{r,v} (VF^x)^n \rightarrow X_2(\gamma) \times \phi_{\gamma,v} (VF^x)^n$ with $rv(Jcbr(G_\gamma))(x) = \delta(x)$. As in Lemma 2.3 one can extend the $G_\gamma$ by compactness to definable sets containing $\gamma$, cover $X_1$ by finitely many such definable sets, and glue together to obtain a single function $G$ with the same property.

\[ \square \]

**Remark** Assume $Id_X : (X, \phi_1) \rightarrow (X, \phi_2)$ has Jacobian 1 everywhere. Then it is possible to find $F$ that is everywhere differentiable, of Jacobian precisely equal to 1. At the before the point where Hensel’s lemma is quoted, it is possible to multiply the function by $J(F)^{-1}$ (not affecting the reduction, since $J(F) \in 1 + M$.) Then one obtains on each such coset a function of Jacobian 1, and therefore globally.

**Example** Let $\phi_2(x) = \phi_1(x)^m$. A definable bijection

\[ X \times \phi_{r,v} (VF^x)^n \rightarrow X \times \phi_{\gamma,v} (VF^x)^n \]

is given by $(x, y) \mapsto (x, y^m)$. (If $rv(u) = \phi(x)^m$, there exists a unique $y$ with $rv(y) = \phi(x)$ and $y^m = u$.)

**Example 6.4.** Proposition 6.1 need not remain valid over an RV-generated base set. Let $A = d(c(e)), e$ a transcendental point of $k$. Let $f_1(y) = y, f_2(y) = 1, L(Y, f) := VF \times f, I = \{x, y \in RV \times Y : rv(x) = y\}$. Then $L(Y, f), L(Y, f')$ are both open balls; over any field $A'$ containing $A$, they are definably isomorphic, using a translation. But these balls are not definably isomorphic over $A$.

7. Special bijections and RV-blowups

We work with a $V$-minimal theory $T$. Recall the lift $L : RV[\leq n, \cdot] \rightarrow VF[n, \cdot]$, with $\rho_X : LX \rightarrow X$. Our present goal is an intrinsic description in terms of RV of the congruence relation: $LX \simeq LY$.

$A$ will denote a $(VF, \Gamma, RV)$-generated substructure of a model of $T$. Note that $T_A$ is also $V$-minimal (Corollary 3.39) so any lemma proved for $T$ under our assumptions can be used for any $T_A$.

The word “definable” below refers to $T$. The categories $VF, RV[s]$ defined below thus depend on $T$; when necessary, we will denote them $VF_T, etc. When $T$ has the form $T = T_A$ for fixed $T^0$ but varying $A$, we write $VF_A, etc.

7.1. Special bijections. Let $X \subseteq VF^{n+1} \times RV^m$ be $\sim$, $\sim$-invariant. Say

\[ X = \{(x, y, u) \in VF \times VF^m \times RV^m : (rv(x), rv(y), u) \in \bar{X}\} \]

(We allow $x$ to be any of the $n+1$ coordinates, $y$ the others.)

Let $s(y, u)$ be a definable function into $VF$ with $\sim$-invariant domain of definition

\[ \dom(s) = \{(y, u) : (rv(y), u) \in \bar{S}\} \]

and $\theta(u)$ a definable function on $pr_u(\dom(s))$ into $RV$, such that $(s(y, u), y, u) \in X$ and $rv(s(y, u)) = rv(y) = rv(x) = \theta(u)$ for $(y, u) \in \dom(s)$. Note that $\theta$ is uniquely defined (given $s$) if it exists. Let

\[ X_1 = \{(x, y, u) \in X : (rv(y), u) \in \bar{S}, rv(x) = \theta(u)\}, \quad X_2 = X \setminus X_1 \]

\[ X_1' = \{(x, y, u) \in VF \times \dom(s) : \val(x) > \val, \theta(u)\} \]
and let $X' = X'_1 \cup X_2$. Also define $e_s : X' \to X$ to be the identity on $X_2$, and

$$e_s(x, y, u) = (x + s(y, u), y, u)$$
on $X'_1$.

**Definition 7.1.** $e_s : X' \to X$ is a definable bijection, called an elementary bijection. \hfill \Box

**Lemma 7.2.**

1. If $X$ is $\sim$-invariant, so is $X'$. If $X \to VF^{n+1}$ is finite-to-one, the same is true of $X'$.
2. If $X_i = L\bar{X}_i$, $X'_i = L\bar{X}'_i$, then $\bar{X}'_i$ is isomorphic to $(RV_i^{>0} \cup \{1\}) \times S$, while $\bar{X}_i$ is isomorphic to $S$.
3. If the projection $X \to VF^{n+1}$ has finite fibers, then so do the projection $\text{dom}(s) \to VF^n$, and also the projection $\bar{S} \to RV^n$, $(y', u) \to y'$.
4. $e_s$ has partial derivative matrix $I$ everywhere, hence has Jacobian 1. Thus if $F : X \to Y$ is such that $\text{r}v\text{J}c\text{b}F$ factors through $\rho_X$, then $\text{r}v\text{J}c\text{b}(F \circ e_s)$ factors through $\rho_X$.

**Proof.** (1,4) are clear. The first isomorphism of (2) is obtained by dividing $x$ by $\theta(u)$, the second is evident. For (3), note that if $(y, u) \in \text{dom}(s)$ then $(s(y, u), y, u) \in X$ so by the assumption $u \in \text{acl}(y, s(y, u))$. But for fixed $y$, $\{s(y, u) : u \in \text{dom}(s)\}$ is finite, by Lemma 3.1. So in fact $(y, u) \in \text{dom}(s)$ implies $u \in \text{acl}(y)$. Hence $(y', u) \in \bar{S}$ implies $u \in \text{acl}(y)$ for any $y$ with $\text{r}v(y) = y'$, so (fixing such a $y$) $\{u : (y', u) \in \bar{S}\}$ is finite for any given $y'$. \hfill \Box

A special bijection is a composition of elementary bijections and auxiliary bijections

$$(x_1, \ldots, x_n, u) \mapsto (x_1, \ldots, x_n, u, \text{rv}(x_1), \ldots, \text{rv}(x_n)).$$

An elementary bijection depends on the data $s$ of a partial section of $X \to VF^n \times RV^m$.

Conversely, given $s$, if $\text{r}v(s(y, u))$ depends only on $u$ we can define $\theta(u) = \text{r}v(s(y, u))$ and obtain a special bijection. If not, we can apply an auxiliary bijection to $X \subseteq VF^n \times RV^m$, and obtain a set $X' \subseteq VF \times RV^{m+n}$, such that $\text{r}v(x) = \text{r}v(m+1)(u)$ for $(x, u) \in X'$. For such a set $X'$, the condition for existence of $\theta$ is automatic and we can define an elementary bijection $X'' \to X'$ based on $s$, and obtain a special bijection $X'' \to X$ as the composition.

The classes of auxiliary morphisms and elementary morphisms are all closed under disjoint union with any identity morphism, and it follows that the class special morphisms under disjoint unions.

### 7.2. Special bijections in one variable and families of RV-valued functions.

We consider here special bijections in dimension 1. An elementary bijection $X' \to X$ in dimension one involves a finite set $B$ of $\text{rv}$-balls, and a set of “centers” of these balls (i.e., a set $T$ containing a unique point $t(b)$ for each $b \in B$), and translates each ball so as to be centered at 0 (while fixing the $\text{rv}$ coordinates). We say that $X' \to X$ blows up the balls in $B$, with centers $T$.

Given a special bijection $h' : X' \to X$, let $F_{n\text{RV}}(X; h')$ be the set of definable functions $X \to RV$ of the form $H(\rho_X((h')^{-1}(x)))$, where $H$ is a definable function. This is a finitely generated set of definable functions $X \to RV$. There will usually be no ambiguity in writing $F_{n\text{RV}}(X, X' \to X)$ instead.

Note that while a special morphism is an isomorphism in VF, an asymmetry exists if $e : X' \to X$ is a special bijection, then $F_{n\text{RV}}(X, X) \subseteq F_{n\text{RV}}(X, X' \to X)$, usually properly.

What is the effect on $F_{n\text{RV}}$ of passing from $X'$ to $X''$, where $X'' \to X'$ is a special bijection? The auxiliary bijections have no effect. Assume $\text{rv}$ is already a coordinate function of $X'$. Consider an elementary bijection $e_s : X'' \to X'$. Let $B = \{(x, u) : u \in \text{dom}(s)\}$. Then the characteristic function $\text{id}_B$ lies in $F_{n\text{RV}}(X', \text{id}_X)$; so $1_B \circ (h')^{-1}$ lies in $F_{n\text{RV}}(X, h')$. Using this, we see that $F_{n\text{RV}}(X', e_s)$ is generated over $F_{n\text{RV}}(X', \text{id}_X)$ by the function $B \to RV$, $(x, u) \mapsto \text{rv}(x - s(u))$. (Extended by 0 outside $B$.) Thus if $h'' = h' \circ e_s : X'' \to X$, $F_{n\text{RV}}(X, h'')$
is generated over $F_n^{RV}(X, h')$ by the composition of the function $(x, u) \mapsto rv(x - s(u))$ with $(h')^{-1}$.

Conversely, if $B$ is a finite union of open balls whose characteristic function lies in $F_n^{RV}(X, h')$, and if there exists a definable set $T$ of representatives (one point $t(b)$ in each ball $b$ of $B$), and a function $\phi = (\phi_1, \ldots, \phi_n)$, $\phi_i \in F_n^{RV}(X, h')$, with $\phi$ injective on $T$, then one can find a special bijection $X'' \to X'$ with composition $h'' : X'' \to X$, such that $F_n^{RV}(X, h'')$ is generated over $F_n^{RV}(X, h')$ by $y \mapsto rv(y - t(y))$, $y \in b \in B$. Namely let $\text{dom}(s) = \phi(T)$, and for $u \in \text{dom}(s)$ set $s(u) = h''^{-1}(t)$ if $t \in T$ and $\phi(t) = u$. In this situation, we will say that the balls in $B$ are blown up by $X'' \to X'$, with centers $T$. Let $\theta(u) = rv(s(u))$. Because $X' \to X$ may already have blown up some of the balls in $B$, $F_n^{RV}(X, h'')$ is generated over $F_n^{RV}(X, h')$ by the restriction of $y \mapsto rv(y - t(y))$ to some sub-ball of $b$, possibly proper. Nevertheless, we have:

**Lemma 7.3.** The function $y \mapsto rv(y - t(y))$ on $B$ lies in $F_n^{RV}(X, h'')$.

**Proof.** This follows from the following more general

**Claim** Let $c \in VF, b \in \mathfrak{B}$ be definable, with $c \in b$. Let $b'$ be an $rv$-ball with $c \in b'$. Then the function $rv(x - c)$ on $b$ is generated by its restriction to $b'$, $rv$, and the characteristic function of $b$.

**Proof.** Let $x \in b \setminus b'$. From $rv(x)$ compute $\text{val}(x)$. If $\text{val}(x) < \text{val}(c)$, $rv(x - c) = rv(c)$. If $\text{val}(x) > \text{val}(c)$, $rv(x - c) = rv(x)$. When $\text{val}(x) = \text{val}(c)$, but $x \notin b'$, $rv(x - c) = rv(x) - rv(c)$. Recall here that $\text{val}_c^{-1}(\gamma)$ is the nonzero part of a $k$-vector space; subtraction, for distinct elements $u, v$, can therefore be defined by $u - v = u(u^{-1}v - 1)$.

Thus any special bijection can be understood as blowing up a certain finite number of balls (in a certain sequence and with certain centers.) We will say that a special bijection $X'' \to X'$ is subordinate to a given partition of $X$ if each ball blown up by $X'' \to X'$ is contained in some class of the partition.

It will sometimes be more convenient to work with the sets of functions $F_n^{RV}(X, h)$ than with the special bijections $h$ themselves.

We observe that any finite set of definable functions $X \to RV$ is contained in $F_n^{RV}(X; h)$ for some $X', h$:

**Lemma 7.4.** Let $X \subseteq VF \times RV^*$ be $\sim$-invariant, and let $f : X \to (RV \cup \Gamma)$ be a definable map. Then there exists a $\sim$-invariant $\pi' : X \subseteq VF \times RV^*$ a special bijection $h : X' \to X$, and a definable function $t$ such that $t \circ \rho_{X'} = f \circ h$. Moreover, if $X = \cup_{i=1}^m P_i$ is a finite partition of $X$ into sets whose characteristic functions factor through $\rho$, we can find $X' \to X$ subordinate to this partition.

**Proof.** Say $X \subseteq VF \times RV^*$; let $\pi : X \to VF, \pi' : X \to RV^m$ be the projections. Applying an auxiliary bijection, we may assume $rv(\pi(x)) = pr_m \pi'(x)$, i.e. $rv(\pi(x))$ agrees with one of the coordinates of $\pi'(x)$. We now claim that there exists a finite $F' \subseteq RV^m$, such that away from $\pi'^{-1}(F')$, $f$ factors through $\pi'$. To prove this, suffice it to show that if $p$ is a complete type of $X$ and $\pi'_*p$ is non-algebraic (i.e. not contained in a finite definable set), then $f[p$ factors through $\pi'$; this follows from Lemma 3.20.

We can thus restrict attention to $\pi'^{-1}(F')$; our special bijections will be the identity away from this. So we may assume $\pi'(X)$ is finite. Recall that (since an auxiliary bijection has been applied) $rv$ is constant on each fiber of $\pi'$. In this case there is no problem relativizing to each fiber of $\pi'$, and then collecting them together (Lemma 2.3), we may assume in fact that $\pi'(X)$ consists of a single point $\{u\}$. In this case the partition (since it is defined via $\rho$) will automatically be respected.
The rest of the proof is similar to Lemma 4.2. We consider first functions $f$ with finite support $F$ (i.e., $f(x) = 0$ for $x \notin F$) and prove the analog of the statement of the lemma for them. If $F = \{0\} \times \{u\}$ then $F = \rho^{-1}(\{(0)\} \times \{u\})$ so the claim is clear. If $F = \{(x_0, u)\}$ let $s : \{u\} \to VF$, $s(u) = x_0$. Applying $e_s$ returns us to the previous case. If $F = F_0 \times \{u\}$ has more than one point, we use induction on the number of points. Let $s(u)$ be the average of $F_0$. Apply the special bijection $e_s$. Then the result is a situation where $rv$ is no longer constant on the fiber. Applying a auxiliary bijection to make it constant again, the fibers of $F \to RV^{m+1}$ become smaller.

The case of the characteristic function of a finite union of balls is similar (following Lemma 4.2.)

Now consider a general function $f$. Having disposed of the case of characteristic function, it suffices to treat $f$ on each piece of any given partition. Thus we can assume $f$ has the form of Corollary 4.4, $f(x) = H(rv(x - n(x)))$. Translating by the $n(x)$ as in the previous cases, we may assume $n(x) = 0$. But $t$ then again $f$ factors through $\rho$ and $rv$, so one additional auxiliary bijection suffices.

\begin{corollary}
Let $X, Y \subseteq VF^n \times RV^*$, and let $f : X \to Y$ be a definable bijection. Then there exists a special bijection $h : X' \to X$, and $t$ such that $p_Y \circ (f \circ h) = t \circ p_X.$

It can be found subordinate to a given finite partition, factoring through $p_X$.
\end{corollary}

We wish to obtain a symmetric version of Corollary 7.5. We will say that bijections $f, g : X \to Y$ differ by special bijections if there exist special bijections $h_1, h_2$ with $h_2g = fh_1$. We show that every definable bijection between $\sim$-invariant objects differs by special bijections from a $\sim$-invariant bijection.

\begin{lemma}
Let $X \subseteq VF \times RV^m$, $Y \subseteq VF \times RV^{m'}$ be definable, $\sim$-invariant; let $F : X \to Y$ be a definable bijection. Then there exist special bijections $h_X : X' \to X$, $h_Y : Y' \to Y$, and an $\sim$-invariant bijection $F' : X' \to Y'$ with $F = h_Y F' h_X^{-1}$. I.e. $F$ differs from an $\sim$-invariant morphism by special bijections.
\end{lemma}

\begin{proof}
It suffices to find $h_X, h_Y$ such that $Fn^{RV}(X, h_X) = F \circ Fn^{RV}(Y, h_Y)$; for then we can let $F' = h_Y^{-1} F h_X$.

Let $X = \bigcup_{i=1}^n P_i$ be a partition as in Proposition 5.1. By Lemma 7.4, there exist $X_0, Y_1$ and special bijections $X_0 \to X, Y_1 \to Y$, such that the characteristic functions of the sets $P_i$ (respectively the sets $F(P_i)$) are in $Fn^{RV}(X, X_0 \to X) (\text{respectively } Fn^{RV}(Y, Y_1 \to Y))$.

By Corollary 7.5, one can find a special $X_1 \to X_0$ such that $Fn^{RV}(X, X_1 \to X)$ contains $F \circ Fn^{RV}(Y, Y_1 \to Y)$. By another application of the same, one can find a special bijection $Y_1 \to Y_1$ subordinate to $\{F(P_i)\}$ such that

\begin{equation}
Fn^{RV}(Y, Y_1 \to Y) \supseteq F^{-1} \circ Fn^{RV}(X, X_1 \to X)
\end{equation}

Now $Y_\ast$ is obtained by composing a sequence $Y_\ast = Y_m \to \ldots \to Y_1$ of elementary bijections and auxiliary bijections. We define inductively $X_m \to \ldots \to X_2 \to X_1$, such that

\begin{equation}
Fn^{RV}(Y, Y_k \to Y) \circ F \subseteq Fn^{RV}(X, X_k \to X)
\end{equation}

Let $k \geq 1$. $Y_{k+1}$ is obtained by blowing up a finite union of balls $B$ of $Y$, with definable set $T$ of representatives such that some $\phi \in Fn^{RV}(Y, Y_k \to Y)$ is injective on $T$; and then $Fn^{RV}(Y, Y_{k+1} \to Y)$ is generated over $Fn^{RV}(Y, Y_k \to Y)$ by $\psi$, where for $y \in B \psi(y) = rv(y - t(b))$ (Lemma 7.3). By the choice of the partition $\{P_i\}$, $F^{-1}(B)$ is also a finite union of balls.
Now \( F^{-1}(B) \), with center set \( F^{-1}(T) \), can serve as data for a special bijection: the requirement about the characteristic function of \( B \) and the injective function on \( T \) being in \( F_n^{RV} \) are satisfied by virtue of Lemma 7.3. We can thus define \( X_{k+1} \to X_k \) so as to blow up \( F^{-1}(B) \) with center set \( F^{-1}(T) \). By Lemma 5.4, \( rv(F(x) - F(x')) \) is a function of \( rv(z - z') \) (and conversely) on each of these balls, so \( F_n^{RV}(X, X_{k+1} \to X) \) is generated over \( F_n^{RV}(X, X_k) \) by \( \psi \circ F \). Hence (7) remains valid for \( k + 1 \).

Now by (6), \( F_n^{RV}(X, X_k \to X) \subseteq F_n^{RV}(Y, Y_m \to Y) \circ F \); since the generators match at each stage, by induction on \( k \leq m \)

\[
F_n^{RV}(X, X_k \to X) \subseteq F_n^{RV}(Y, Y_m \to Y) \circ F \tag{8}
\]

By (7) and (8) for \( k = m \), \( F_n^{RV}(X, X_m \to X) = F_n^{RV}(Y, Y_m \to Y) \circ F \)

For the sake of possible future refinements, we note that the proof of Lemma 7.6 shows also:

**Lemma 7.7.** Let \( X \subseteq VF \times RV^m \), \( Y \subseteq VF \times RV^m \) be definable, \( \sim \)-invariant; let \( F : X \to Y \) be a definable bijection. If a Proposition 5.1 - partition for \( F \) has characteristic functions factoring through \( \rho_X \times \rho_Y \), and if \( F \) is \( \sim \)-invariant, then for any special bijection \( h'_X : X' \to X \) there exists a special bijection \( h'_Y : Y' \to Y' \) such that \( (h'_Y)^{-1} F h'_X \) is \( \sim \)-invariant.

7.3. Several variables. We will show now in general that any definable map from an \( \sim \)-invariant object to \( RV \) factors through the inverse of a special bijection, and the standard map \( \rho \).

**Lemma 7.8.** Let \( X \subseteq VF^n \times RV^m \) be \( \sim \)-invariant, and let \( \phi : X \to (RV \cup \Gamma) \). Then there exists a special bijection \( h : X' \to X \), and a definable function \( \tau \) such that \( \tau \circ \rho_X = \phi \circ h \).

**Proof.** By induction on \( n \). For \( n = 0 \) we can take \( X' = X \), since \( \rho_X = Id_X \).

For \( n = 1 \) and \( X \subseteq VF \), by Lemma 7.4, there exists \( \mu = \mu(X, \phi) \in \mathbb{N} \) such that the lemma holds for some \( h \) that is a composition of \( \mu \) elementary and auxiliary bijections. It is easy to verify the semi-continuity of \( \mu \) with respect to the definable topology: if \( X_k \) is a definable family of definable sets, so that \( X_k \) is \( A(b) \)-definable, and \( \mu(X_k, \phi | X_k) = m \), then there exists a definable set \( D \) with \( b \in D \) and such that if \( b' \notin D \), then \( \mu(X_k', \phi | X_k') \leq m \).

Assume the lemma known for \( n \) and suppose \( X \subseteq VF \times Y \) with \( Y \subseteq VF^m \times RV^n \). For any \( b \in Y \), let \( X_b = \{ x : (x, b) \in X \} \subseteq VF \); so \( X_b \) is \( A(b) \)-definable.

Consider first the case \( \mu = 0 \). Then \( \phi | X_b = \tau_0 \circ \rho_X | X_b \), for some \( A(b) \)-definable function \( \tau_0 : RV^m \to (RV \cup \Gamma) \). By stable embeddedness and elimination of imaginaries in \( RV \cup \Gamma \), there exists (§2.1.5) a canonical parameter \( d \in (RV \cup \Gamma)' \), and an \( A \)-definable function \( \tau \), such that \( \tau_0(t) = \tau(d, t) \); and \( d \) itself is definable from \( \tau_0 \), so we can write \( d = \delta(b) \) for some definable \( \delta : Y \to (RV \cup \Gamma)' \). Using the induction hypothesis for \( (Y, \delta) \) in place of \( (X, \phi) \), we find that there exists a \( \sim \)-invariant \( Y' \subseteq VF^n \times RV^m \), a special \( h_Y : Y' \to Y' \), and a definable \( \gamma_Y \), such that \( \gamma_Y \circ \rho_Y = \delta \circ h_Y \). Let \( X' = X \times Y' \), \( h(x, y) = (x, h_Y(y')) \), An elementary bijection to \( Y \) determines one to \( X \), where the function \( s \) does not make use of the first coordinate; so \( h : X' \to X \) is special. In this case the lemma is proved: \( \phi \circ h(x, y) = \phi(x, h_Y(y')) = \tau_0(h_Y(y'), \rho(x, y)) = \tau_0(\rho_Y(y'), \rho(x, y)) \).

Next suppose \( \mu > 0 \). Applying an auxiliary bijection, we may assume that for some definable function (in fact projection) \( p, rv(x) = p(u) \) for \( (x, y, u) \in X \). For each \( b \in Y(M) \) (with \( M \) any model of \( T_A \)) there exists an elementary bijection \( h_b : X_b' \to X_b \) such that \( \mu(X_b, \phi | X_b) < \mu \); \( h_b \) is determined by \( s_b, \theta_b \) with \( s_b \in rv(s_b) = \theta_b, \) and \( (s_b, \theta_b) \in X \). (The \( u \)-variables have been absorbed into \( b \).) By compactness, one can take \( s_b = s(b) \) and \( \theta_b = \theta(b) \) for some definable
functions $s, \theta$. By the inductive hypothesis applied to $(Y, \theta')$, as in the previous paragraph, we can assume $\theta'(y, u) = \theta(u)$ for some definable $\theta$. Applying the special bijection with data $(s, \theta)$ now amounts to blowing up $(s_0, \theta_h)$ uniformly over each $b$, and thus reduces the value of $\mu$.  

**Question 7.9.** Is Proposition 7.6 true in higher dimensions?  

**Corollary 7.10.** Let $X \subseteq \mathbb{VF}^n \times \mathbb{RV}^m$ be definable. Then every definable function $\phi : X \to \Gamma$ factors through a definable function $X \to \mathbb{RV}^*$.  

**Proof.** By Lemma 4.5 we may assume $X$ is $\sim$-invariant; now the corollary follows from Lemma 7.8.

(It is convenient to note this here, but it can also be proved with the methods of §3; the main point is that on the generic type of a ball with center $c$, every function into $\mathbb{RV} \cup \Gamma$ factors through $r(x - c)$; while on a transitive ball, every function into $\mathbb{RV} \cup \Gamma$ is constant.)

Consider pairs $(X', f')$ with $X', f' : X' \to \mathbb{VF}^n$ definable, and such that $f'$ has $\mathbb{RV}$-fibers. A bijection $g : X' \to X''$ is said to be relatively unary (with respect to $f', f''$) if it commutes with $n - 1$ coordinate projections, i.e., $pr_i f'' g = pr_i f'$ for all but at most one value of $i$.

Given $X \subseteq \mathbb{VF}^n \times \mathbb{RV}^m$, we view its as a pair $(X, f)$ with $f$ the projection to $\mathbb{VF}^n$. Thus for $X, Y \subseteq \mathbb{VF}^n \times \mathbb{RV}^*$, the notion: $F : X \to Y$ is relatively unary is defined.

Note that the elementary bijections are relatively unary, as are the auxiliary bijections.

**Lemma 7.11.** Let $X, Y \subseteq \mathbb{VF}^n \times \mathbb{RV}^*$, and let $F : X \to Y$ be a definable bijection. Then $F$ can be written as the composition of relatively unary morphisms of $\mathbb{VF}[n, \,]$.

**Proof.** We have $X$ with two finite-to-one maps $f, g : X \to \mathbb{VF}^n$ (the projection, and the composition of $F$ with the projection $Y \to \mathbb{VF}^n$). We must decompose the identity $X \to X$ into a composition of relatively unary maps $(X, f) \to (X, g)$.

Begin with the case $n = 2$; we are given $(X, f_1, f_2)$ and $(X, g_1, g_2)$.

**Claim** There exists a definable partition of $X$ into sets $X_{ij}$ such that $(f_i, g_j) : X \to \mathbb{VF}^2$ is finite-to-one.

**Proof.** Let $a \in X$. We wish to show that for some $i, j$, $a \in acl(f_i(a), g_j(a))$. This follows from the exchange principle for algebraic closure in $\mathbb{VF}$: if $a \in acl(\emptyset)$, there is nothing to show. Otherwise $g_j(a) \notin acl(\emptyset)$ for some $j$; in this case either $a \in acl(f_1(a), g_j(a))$ or $f_i(a) \in acl(g_j(a))$, and then $a \in acl(f_i(a), g_j(a))$. The Claim follows by compactness.

Let $h : X' \to X$ be a special bijection such that the characteristic functions of $X_{ij}$ are in $Fh_{\mathbb{RV}}(X, X' \to X)$ (Lemma 7.8). Since $h$ is composition of relatively unary bijections, we may replace $X$ by $X'$ (and $f_i, g_i$ by $f_i \circ h, g_i \circ h$ respectively.) So we may assume the characteristic function of $X_{ij}$ is in $Fn_{\mathbb{RV}}(X, X)$, i.e. $X_{ij} \in \mathbb{VF}[n]$. But then it suffices to treat each $X_{ij}$ separately; say $X_{11}$. In this case the identity map on $X$ takes

$$(X, f_1, f_2) \mapsto (X, f_1, g_1) \mapsto (X, g_2, g_1) \mapsto (X, g_1, g_1 - g_2) \mapsto (X, g_1, g_1 - g_2) \mapsto (X, g_1, g_2)$$

where each step is relatively unary.

When $n > 2$, we move between $(X, f_1, \ldots, f_n)$ and $(X, g_1, \ldots, g_n)$, by partitioning, and on a given piece replacing each $f_i$ by some $g_j$, one at a time.

**7.4. RV-blowups.** We now define the RV-counterparts of the special bijections, which will be called RV-blowups. These will not be bijections; the kernel of the homomorphism $L : K_+[\mathbb{RV}] \to K_+ [\mathbb{VF}]$ will be seen to be obtained by formally inverting RV-blowups. Let $\mathbb{RV}^\infty = \{ x \in \mathbb{RV} : val(x) > 0 \cup \{ \infty \} \} \subseteq \mathbb{RV}_\infty$. In the $\mathbb{RV}[1]$-presentation, $\mathbb{RV}^\infty = [\mathbb{RV}^\infty] + [1]_0$. (cf. §3.8.1).
Definition 7.12. (1) Let \( Y = (Y, f) \in \text{Ob} \, \text{RV}_\infty[n, \cdot] \) be such that \( f_n(y) \in \text{acl}(f_1(y), \ldots, f_{n-1}(y)) \), and \( f_n(y) \neq \infty \). Let \( Y' = Y \times \text{RV}^{\geq 0}_\infty \). For \( (y, t) \in Y' \), define \( f' = (f'_1, \ldots, f'_n) \) by: \( f'_i(y, t) = f_i(y) \) for \( i < n \), \( f'_n(y, t) = t f_n(y) \). Then \( \bar{Y} = (Y', f') \) is an elementary blowup of \( Y \). It comes with the projection map \( Y' \to Y \).

(2) Let \( X = (X, g) \in \text{Ob} \, \text{RV}_\infty[n, \cdot] \), \( X = X' \cup X'' \), \( g' = g|X' \), \( g'' = g|X'' \), and let \( \phi : Y \to (X', g') \) be an \( \text{RV}_{\text{vol}} \)-isomorphism. Then the \( \text{RV} \)-blowup \( \bar{X}_\phi \) is defined to be \( \bar{Y} + (X''', g''') = (Y' \cup X'', f' \cup g'') \). It comes with \( b : Y' \cup X'' \to X \), defined to be the identity on \( X'' \), and the projection on \( Y' \). \( X' \) is called the blowup locus of \( b : \bar{X}_\phi \to X \).

An iterated \( \text{RV} \)-blowup is obtained by finitely many iterations of \( \text{RV} \)-blowups.

Since blowups in the sense of algebraic geometry will not occur in this paper, we will say ‘blowup’ for \( \text{RV} \)-blowup.

Remark 7.13. In the definition of an elementary blowup, dim_{\text{RV}}(Y) < n. For such \( Y \), \( \phi : Y \to (X', g') \) is an \( \text{RV}_{\text{vol}}[\leq n, \cdot] \)-isomorphism if it is an \( \text{RV}_{\text{vol}}[= n, \cdot] \)-isomorphism (Definition 5.21).

Lemma 7.14. (1) Let \( Y' \) be an elementary blowup of \( Y \). \( Y' \) is \( \text{RV}_{\text{vol}}[n, \cdot] \)-isomorphic to \( Y'' = (Y'', f'') \), with \( Y'' = \{(y, t) \in Y \times \text{RV}_\infty : \text{val}_v(t) > f_n(y) \} \), \( f''(y, t) = (f_1(y), \ldots, f_{n-1}(y), t) \).

(2) An elementary blowup \( Y' \) of \( Y \) is \( \text{RV}_\infty[n, \cdot] \)-isomorphic to \( (Y \times \text{RV}_\infty, f') \) for any \( f' \) isogenous to \( (f_1, \ldots, f_n) \).

(3) Up to isomorphism, the blowup depends only on blowup locus. In other words if \( X, X', g, g' \) are as in Definition 7.12, and \( \phi_i : Y_i \to (X', g') \) \( (i = 1, 2) \) are isomorphisms, then \( \bar{X}_\phi, \bar{X}_{\phi_2} \) are \( X \)-isomorphic in \( \text{RV}_{\text{vol}}[n, \cdot] \).

Proof. (1) The isomorphism is given by \( (y, t) \mapsto (y, t f_n(y)) \).

(2) The identity map on \( Y \times RV \) is an \( \text{RV}_\infty[n, \cdot] \)-isomorphism.

(3) Let \( \psi_0 = \phi_2^{-1} \phi_1 \), and define \( \psi_i : Y_2 \times \text{RV}^{\geq 0}_\infty \to Y_2 \times \text{RV}^{\geq 0}_\infty \) by \( (p_0(y), t) \mapsto (p_0(y), t) \). The sum of the values of the \( n \) coordinates of \( \bar{Y}_i \) is then \( (\sum_{i<n} \text{val}_v f_i) + (\text{val}_v t + \text{val}_v f_n) \) in both cases. Since by assumption \( \psi_0 : Y_2 \to Y_2 \) is an \( \text{RV}_{\text{vol}} \)-isomorphism, it preserves \( \sum_{i<n} \text{val}_v f_i \) and so \( \psi_0 \) too is an \( \text{RV}_{\text{vol}} \)-isomorphism; thus \( \text{Jcb}_{\text{RV}}(\psi_0) \in [\text{K}^* \cdot \text{K}^*] \). Let \( \theta \phi_1 \to \text{K}^* \) be a definable map such that \( \theta = \text{Jcb}_{\text{RV}}(\psi_0) \). Then one computes immediately that \( \text{Jcb}_{\text{RV}}(\psi) = 1 \), so \( \psi \) is an \( \text{RV}_{\text{vol}}[n, \cdot] \)-isomorphism, and hence so is \( \psi \cup \text{Id}_X : \bar{X}_\phi \to \bar{X}_{\phi_2} \).

Here is a coordinate-free description of RV-blowups; we will not really use it in the subsequent development.

Lemma 7.15. (1) Let \( Y = (Y, g) \in \text{Ob} \, \text{RV}_\infty[n, \cdot] \), with \( \text{dim}(g(Y)) < n \); let \( f : Y \to \text{RV}^{n-1}_\infty \) be isogenous to \( g \). Let \( h : Y \to \text{RV} \) be definable, with \( h(y) \in \text{acl}(g(y)) \) for \( y \in Y \), and with \( \sum_{i<n} (g) = \sum (f) + \text{val}_v(h) \). Let \( Y' = Y \times \text{RV}^{\geq 0}_\infty \), and \( f'(y, t) = (f(y), th(y)) \). Then \( \bar{Y}' = (Y', f') \) with the projection map to \( Y \) is a blowup.

(2) Let \( Y'' \to Y \) be a blowup with blowup locus \( Y \). Then there exist \( f, h \) such that with \( Y' \) as in (3), \( Y'', Y' \) are isomorphic over \( Y \).

Proof. (1) Since \( \text{dim}_{\text{RV}}(g(Y)) < n \), \( \text{Id}_{Y} : (Y, (f, h)) \to (Y, g) \) is an \( \text{RV}_{\text{vol}} \)-isomorphism. Use this as \( \phi \) in the definition of blowup.

(2) With notation as in Definition 7.12, let \( h = g_n \circ \phi^{-1} \), \( f = (g_1, \ldots, g_{n-1}) \circ \phi^{-1} \).

Definition 7.16. For $\mathcal{C} = \text{RV}[\leq n, :]$ or $\mathcal{C} = \text{RV}_{\text{vol}}[\leq n, :]$ let $\text{Isp}[\leq n]$ be the set of pairs $(X_1, X_2) \in \text{Ob} \mathcal{C}$ such that there exist iterated blowups $b_i : X_1 \to X_i$ and an $\mathcal{C}$-isomorphism $F : \tilde{X}_1 \to \tilde{X}_2$.

When $n$ is clear from the context, we will just write $\text{Isp}$.

Definition 7.17. Let $1_0$ denote the one-element object of $\text{RV}[0]$. Given a definable set $X \subseteq \text{RV}^n$ let $X_n$ denote $(X, \text{Id}_X) \in \text{RV}[n]$, and $[X]_n$ the class in $K_+(\text{RV}[n])$. Write $[1]$ for $\{1\}_1$ (where $\{1\}$ is the singleton set of the identity element of $k_+$.)

Lemma 7.18. Let $\mathcal{C} = \text{RV}[\leq n, :]$ or $\mathcal{C} = \text{RV}_{\text{vol}}[\leq n, :]$.

1. Let $f : X_1 \to X_2$ be an $\mathcal{C}$-isomorphism, and let $b_1 : X_1 \to X_1$ be a blowup. Then there exists a blowup $b_2 : \tilde{X}_2 \to X_2$ and an $\mathcal{C}$-isomorphism $F : \tilde{X}_1 \to \tilde{X}_2$ with $b_2 F = f b_1$.

2. If $\tilde{X} \to X$ is a blowup, then so are $\tilde{b}_1 \cup \text{Id} : \tilde{X} \cup Z \to \tilde{X} \cup Z$ and $(b \times \text{Id}) : \tilde{X} \times Z \to \tilde{X} \times Z$.

3. Let $b_i : \tilde{X}_{\phi_i} \to \tilde{X}$ be a blowup ($i = 1, 2$). Then there exist blowups $b'_i : Z_i \to \tilde{X}_{\phi_i}$ and an isomorphism $F : Z_1 \to Z_2$ such that $b_2 b'_2 F = b_1 b'_1$.

4. Same as (1,2,3) for iterated blowups.

5. $\text{Isp}$ is an equivalence relation. It induces a semi-ring congruence on $K_+\text{RV}[*,:]$, respectively $K_+\text{RV}_{\text{vol}}[*,:]$.

6. As a semi-ring congruence on $K_+\text{RV}[*,:]$, $\text{Isp}$ is generated by $\{[1]_1 : [\text{RV}_{\text{vol}}[0, :]+1_0]\}$.

Proof. (1) This reduces to the case of elementary blowups. If $\mathcal{C} = \text{RV}_{\text{vol}}[n, :]$ then the composition $f \circ b_1$ is already a blowup. If $\mathcal{C} = \text{RV}[\leq n, :]$, it is also clear using Lemma 7.14 (2).

(2) From the definition of blowup.

(3) If $b_1$ is the identity, let $b'_1 = b_2 = \text{Id}$, $F = \text{Id}$. Similarly if $b_2$ is the identity. If $X = X' \cup X''$ and the statement is true above $X'$ and above $X''$, then by glueing it is true also above $X$. We thus reduce to the case that $b_1, b_2$ both are blowups with blowup locus equal to $X$. But then by Lemma 7.14 (3), there exists an isomorphism $F : \tilde{X}_{\phi_1} \to \tilde{X}_{\phi_2}$ over $X$. Let $b'_1 = b'_2 = \text{Id}$.

(4) For (1,2) the induction is immediate. For (3), write $k$-blowup as shorthand for “an iteration of $k$ blowups”. We show by induction on $k_1, k'$ a more precise form:

Claim. If $X_1 \to X$ is a $k_1$-blowup, and $X' \to X$ is a $k'$ blowup, then there exists an $k'$-blowup $Z'_1 \to X_1$ a $k_1$-blowup $Z' \to X$, and an $\text{RV}_{\text{vol}}[n, :]$-isomorphism $Z_1 \to Z'$ over $X$.

If $k_1 = k' = 1$ this is (3). So say $k' > 1$. The map $X' \to X$ is a composition $X' \to X_2 \to X$, where $X_2 \to X$ is a $k' - 1$-blowup and $X' \to X_2$ is a blowup. By induction there is a $k' - 1$ blowup $Z_1 \to X_1$ and a $k_1$-blowup $Z_2 \to X_2$ and an $\text{RV}_{\text{vol}}[n, :]$-isomorphism $Z_1 \to Z_2$ over $X$.

By induction again there is a blowup and $Z_2' \to Z_2$, a $k_1$-blowup $Z' \to X'$ an $\text{RV}_{\text{vol}}[n, :]$-isomorphism $Z'_1 \to Z'_2$ over $X$. By (1) there exists a blowup $Z'_1 \to Z_1$ and an $\text{RV}_{\text{vol}}[n, :]$-isomorphism $Z'_1 \to Z'_2$, making the $Z_1, Z_2, Z'_1, Z'_2$-square commute. So $Z_1 \to X_1$ is a $k'$-blowup, $Z' \to X'$ is a $k_1$-blowup, and we have a composed isomorphism $Z'_1 \to Z'_2$ over $X$.

By (1) for iterated blowups there are iterated blowups $X'_1 \to X_1, X'_2 \to X_2$ and an isomorphism $X'_1 \to X'_2; and also $X''_2 \to X_2, X''_3 \to X_3$ and $X''_3 \to X_3$. Using (3) for iterated blowups, there exist iterated blowups $\tilde{X}_2 \to \tilde{X}_2, \tilde{X}_3 \to \tilde{X}_3$, and an isomorphism $\tilde{X}_2 \to \tilde{X}_3$. By (1) for iterated blowups there are iterated blowup $\tilde{X}_1 \to \tilde{X}_1, \tilde{X}_3 \to \tilde{X}_3$ and isomorphisms $\tilde{X}_1 \to \tilde{X}_2, \tilde{X}_2'' \to \tilde{X}_3$, with the natural diagrams commuting. Composing we obtain $\tilde{X}_1 \to \tilde{X}_3$, showing that $(X_1, X_3) \in \text{Isp}$. Hence $\text{Isp}$ is an equivalence relation.
Isomorphic objects are $I_{sp}$-equivalent, so an equivalence relation on the semiring $K_+\mathbb{C}$ is induced. If $(X_1, X_2) \in I_{sp}$ then by (2), $(X_1 \cup Z, X_2 \cup Z) \in I_{sp}$, and $(X_1 \times Z, X_2 \times Z) \in I_{sp}$. It follows that $I_{sp}$ induces a congruence on the semiring $K_+\mathbb{C}$.

(6) We can blow up $1_1$ to $RV^{>0}_1 + 1_0$, so $([1_1], [RV^{>0}_1] + 1_0) \in I_{sp}$. Conversely, under the conditions of Definition 7.12, let $Y^- = [(Y, f_1, \ldots, f_{n-1})]$; then $[Y] = [(Y, f_1, \ldots, f_{n-1}, 0)] = [Y^-] \times [1_1]$ by Lemma 7.14, and we have:

$$\bar{X}_Y = [Y]_{n-1} + [X]_{n-1} \times [RV^{>0}_1] + [X'] \cong I_{sp} [Y] \times [1_1] + [X'] = [X]$$

modulo the congruence generated by $([1_1], [RV^{>0}_1] + 1_0)$. □

We now relate special bijections to blowing ups. Given $X = (X, f), X' = (X', f') \in RV[n, -]$, say $X, X'$ are strongly isomorphic if there exists a bijection $\phi : X \to X'$ with $f' = \phi f$. Strong isomorphisms are always in $RV_{vol}[n, -]$.

Up to strong isomorphism, an elementary blowup of $(Y, f)$ can be put in a different form: $\bar{(Y)} \simeq (Y'', f'')$, $Y'' = \{(z, y) : y \in Y, \text{val}_y(z) > \text{val}_y f_n(y)\}, f_i(z, y) = f_i(y)$ for $i < n$, $f_n(z, y) = z$. The strong isomorphism $Y'' \to Y'$ is given by $(z, y) \mapsto (y, z/f_n(y))$. This matches precisely the definition of special bijection, and makes evident the following lemma.

**Lemma 7.19.** Let $\mathcal{C} = RV_{\infty}[n, -]$ or $RV_{vol}[\leq n, -]$. $X, Y$ are strongly isomorphic over $RV^n$ iff $LY, LX$ are isomorphic over the projection to $VF^n$.

(2) Let $X, X' \in RV[\leq n, -]$, and let $G : LX' \to LX$ be an auxiliary special bijection. Then $X'$ is isomorphic to $X$ over $RV^n$.

(3) Let $X, X' \in RV[\leq n, -]$, and let $G : LX' \to LX$ be an auxiliary special bijection. Then $X'$ is strongly isomorphic to a blowup of $X$.

(4) Let $X, X' \in RV[\leq n, -]$, and let $G : LX' \to LX$ be a special bijection. Then $X'$ is strongly isomorphic to an iterated blowup of $X$.

(5) Assume $T$ is effective. If $Y \to X$ is an RV-blowup, there exists $Y'$ strongly isomorphic to $Y$ over $X$ and an elementary bijection $c : LY' \to LX$ lying over $Y' \to Y$.

**Proof.** (1) Clear, using Lemma 3.52.

(2) This is a special case of (1).

(3) Clear from the definitions.

(4) Clear from (1-3).

(5) It suffices to consider elementary blowups; we use the notation in the definition there. So $f_n(x) \in acl(f_1(x), \ldots, f_{n-1}(x))$ for $x \in \phi(Y)$. By effectiveness and Lemma 6.2 there exists a definable function $s(x, y_1, \ldots, y_{n-1})$ such that if $r_{nv}(y_i) = f_i(x)$ for $i = 1, \ldots, n-1$, then $r_{sv}(x, y) = f_n(x)$. This is the additional data needed for an elementary bijection. □

**Lemma 7.20.** Let $X = (X, f), X' = (X', f') \in RV[\leq n, -], and let h : X \to W \subseteq RV^n, h' : X' \to W$ be definable maps. Let $X_c = h^{-1}(c), X_c = (X_c, f|X_c) and similarly X'_c$. If $(X_c, X'_c) \in I_{sp}(RV_{\infty}[n, -])$ then $(X, X') \in I_{sp}$.

**Proof.** Lemma 2.3 applies to $RV_{\infty}-vol$-isomorphisms, and hence using Remark 7.13 also to blowups. It also applies to $RV[\leq n, -]$-isomorphisms; hence to $I_{sp}$-equivalence. □

**Lemma 7.21.** If $(X, Y) \in I_{sp}$ then $LY \simeq LY$.

**Proof.** Clear, since $L[1_1]$ is the unit open ball around 1, $L[RV^{>0}_1]$ is the punctured unit open ball around 0, and $L[1_0] = \{0\}$. □
7.5. The kernel of $L$.

**Definition 7.22.** $\text{VFR}[k,l,\cdot]$ is the set of pairs $X = (X,f)$, with $X \subseteq \text{VF}^k \times \text{RV}^*$, $f : X \to \text{RV}_{\infty}^l$, and such that $f$ factors through the projection $\text{pr}_\text{RV}(X)$ of $X$ to the RV-coordinates. $\text{I}_\text{sp}$ is the equivalence relation on $\text{VFR}[k,l,\cdot]$:

$$(X,Y) \in \text{I}_\text{sp} \iff (X^a,Y^a) \in \text{I}_\text{sp}(T_\alpha) \text{ for each } a \in \text{VF}^k$$

$K_+ \text{VFR}$ is the set of equivalence classes.

By the usual compactness argument, if $(X,Y) \in \text{I}_\text{sp}$ then there are uniform formulas demonstrating this. The relative versions of Lemmas 7.14, 7.18 follow.

If $U = (U,f) \in \text{VFR}[k,l,\cdot]$, and for $u \in U$ we are uniformly given $V_u = (V_u,g_u) \in \text{VFR}[k',l',\cdot]$ we can define a sum $\sum_{u \in U} V_u \in \text{VFR}[k+k',l+l',\cdot]$: it is the set $\bigcup_{u \in U} V_u$, with the function $(u,v) \to (f(u),g_u(v))$. When necessary, we denote this operation $\sum (k,l;k',l')$. The special case $k = l = 0$ is understood as the default case.

By Proposition 7.6, the inverse of $L : \text{RV}[1,\cdot] \to \text{VF}[1,\cdot]$ induces an isomorphism $I_1^1 : K_+ \text{VF}[1,\cdot] \to K_+ \text{RV}[1,\cdot]/\text{I}_\text{sp}$.

$$I([X]) = [Y]/\text{I}_\text{sp} \iff [LY] = [X]$$

Let $J$ be a finite set of $k$ elements. For $j \in J$, let $\pi_j : \text{VF}^k \times \text{RV}^* \to \text{VF}^{J-\{j\}} \times \text{RV}^*$ be the projection forgetting the $j$'th VF coordinate. We will write $\text{VF}^k,\text{VF}^{k-1}$ for $\text{VF}^J,\text{VF}^{J-\{j\}}$ respectively when the identity of the indices is not important.

Let $X = (X,f) \in \text{VFR}[k,l,\cdot]$. By assumption, $f$ factors through $\pi_j$. We view the image $(\pi_j X,f)$ as an element of $\text{VFR}[k-1,l,\cdot]$. Note that each fiber of $\pi_j$ is in $\text{VF}[1,\cdot]$.

Relativizing $I_1^1$ to $\pi_j$, we obtain a map

$$I^j_j = I_{k,J}^j : \text{VFR}[k,l,\cdot] \to K_+ \text{VFR}[k-1,l+1,\cdot]/\text{I}_\text{sp}$$

**Lemma 7.23.** Let $X = (X,f), X' = (X',f') \in \text{VFR}[k,l,\cdot]$.

1. $I^j$ commutes with maps into $\text{RV}$: if $h : X \to W \subseteq \text{RV}^*$ is definable, $X_c = h^{-1}(c)$, then

$$I^j(X) = \sum_{c \in W} I^j(X_c)$$

2. $I([X],[X']) \in \text{I}_\text{sp}$ then $(I^j(X),I^j(X')) \in \text{I}_\text{sp}$.

3. $I^j$ induces a map $K_+ \text{VFR}[k,l,\cdot]/\text{I}_\text{sp} \to K_+ \text{VFR}[k-1,l+1,\cdot]/\text{I}_\text{sp}$.

**Proof.** (1) This reduces to the case of $I_1^1$, where it is an immediate consequence of the uniqueness, and the fact that $L$ commutes with maps into $\text{RV}$ in the same sense.

(2) All equivalences here are relative to the $k-1$ coordinates of $\text{VF}$ other than $j$, so we may assume $k = 1$.

For $a \in \text{VF}$, $([X_a],[X'_a]) \in \text{I}_\text{sp}(T_\alpha)$. By stable embeddedness of $\text{RV}$, there exists $\alpha = \alpha(a) \in \text{RV}^*$ such that $X_a, X'_a$ are $T_\alpha$-definable and $([X_a],[X'_a]) \in \text{I}_\text{sp}(T_\alpha)$. Fibering over the map $\alpha$ we may assume by (1) and Lemma 7.20 that $\alpha$ is constant; so for some $W \in \text{VF}[1], Y, Y' \in \text{RV}[l,\cdot]$, we have $X = W \times Y, X' = W \times Y'$, and $(Y,[Y']) \in \text{I}_\text{sp}$. Then $I^j(X) = I^j(W) \times Y, I^j(X') = I^j(W) \times Y'$ and the conclusion is clear.

(3) by (2).

**Lemma 7.24.** Let $X = (X,f), X \subseteq \text{VF}^J \times \text{RV}^\infty, f : X \to \text{RV}^J$. If $j \neq j' \in J$ then $I^j I^{j'} = I^j I^{j'} : K_+ \text{VFR}[k,l,\cdot]/\text{I}_\text{sp} \to K_+ \text{VFR}[k-1,l+2,\cdot]/\text{I}_\text{sp}$.
Proof. We may assume \( S = \{1, 2\}, j = 1, j' = 2 \), since all is relative to \( \text{VF}^S \setminus \{j, j'\} \). By Lemma 7.23 (1) it suffices to prove the statement for each fiber of a given definable map into \( \text{RV} \).

Hence we may assume \( X \subseteq \text{VF}^2 \) and \( f \) is constant; and by Lemma 5.10, we can assume \( X \) is a basic 2-cell:

\[
X = \{(x, y) : x \in X_1, rv(y - G(x)) = \alpha_1 \} \quad X_1 = \text{rv}^{-1}(\delta_1) + c_1
\]

The case where \( G \) is constant is easy, since then \( X \) is a finite union of rectangles. Otherwise \( G \) is invertible, and by niceness of \( G \) we can also write:

\[
X = \{(x, y) : y \in X_2, rv(x - G^{-1}(y)) = \beta \}, \quad X_2 = \text{rv}^{-1}(\delta_2) + c_2
\]

We immediately compute:

\[
I_2 I_1 (X) = (\delta_1, \alpha_1), \quad I_1 I_2 (X) = (\alpha_2, \delta_2)
\]

Clearly \([ (\delta_1, \alpha_1) ]_2 = [ (\alpha_2, \delta_2) ]_2 \).

\[ \square \]

**Proposition 7.25.** Let \( X, Y \in \text{RV}[\leq n, \cdot] \). If \( L_X, L_Y \) are isomorphic, then \( ([X], [Y]) \in \text{Isp} \).

**Proof.** Define \( I = I_1 \ldots I_n : \text{VF}[n, \cdot] \to \text{VFR}[0, n, \cdot] = \text{RV}[\leq n, \cdot] \). Let \( V \in \text{VF}[n, \cdot] \).

**Claim 1.** If \( \sigma \in Sym(n) \) then \( I = I_{\sigma(1)} \ldots I_{\sigma(n)} \).

**Proof.** We may assume \( \sigma \) just permutes two adjacent coordinates, say 2, 3 out of 1, 2, 3, 4. Then \( I = I_1 I_2 I_3 I_4 = I_1 I_3 I_2 I_4 \) by Lemma 7.24.

**Claim 2.** When \( F : V \to F(V) \) is a relatively unary bijection, we have \( I(V) = I(F(V)) \).

**Proof.** By Claim 1 we may assume \( F \) is relatively unary with respect to \( \text{pr}^n \). So \( F(V_a) = F(V)_a \) where \( V_a, F(V)_a \) are the \( \text{pr}^n \)-fibers. By definition of \( I^1_a \) we have \( I^1_a (V_a) = I^1_a (F(V)_a) \in \text{RV}[1, \cdot](T_a) \); but by definition of \( I^n \), \( I^n(V)_a = I^n_a (V_a) \). So \( I(V) = I(F(V)) \) and thus \( I(V) = I(F(V)) \).

**Claim 3.** When \( F : V \to F(V) \) is any definable bijection, \( I(V) = I(F(V)) \).

**Proof.** Immediate from Claim 2 and Lemma 7.11.

Now turning to the statement of the Proposition, assume \( L_X, L_Y \) are isomorphic. We compute inductively that \( I(X) = [X] \). By Claim 3, \([X] = I(LX) = I(LY) = [Y] \).

\[ \square \]

**Notation 7.26.** Let \( L^* : K_+(\text{VF}) \to K_+(\text{RV}[\cdot]) \) be the inverse map to \( L \).

**Remark 7.27.** When \( T \) is \( \text{rv} \)-effective, one can restate the conclusion of Proposition 7.25 as follows: if \( X, Y \in \text{VF}[n, \cdot] \) are \( \sim \)-invariant and \( F : X \to Y \) is a definable bijection, then there exist special bijections \( X' \to X \) and \( Y' \to Y \) and an \( \sim \)-invariant -definable bijection \( G : X' \to Y' \). (This follows from Proposition 7.25, Proposition 6.1, Lemma 7.18, and Lemma 7.19. The effectiveness hypothesis is actually unnecessary here, as will be seen in the proof of Proposition 8.26. Perhaps Question 7.9 can be answered simply by tracing the connection between \( F \) and \( G \) through the proof.

8. Definable sets over \( \text{VF} \) and \( \text{RV} \): the main theorems

In stating the theorems we restrict attention to \( \text{VF}[n] \), i.e. to definable subsets of varieties, though the proof was given more generally for \( \text{VF}[n, \cdot] \) (definable subsets of \( \text{VF}^n \times \text{RV}^n \).)
8.1. Definable subsets of varieties. Let \( T \) be \( V \)-minimal. We will look at the category of definable subsets of varieties, and definable maps between them. The results will be stated for \( VF[n] \); analogous statements for \( VF[n,\bar{\bar}i] \) are true with the same proofs.

We define three variants of the sets of objects. \( VF^n[n] \) is the category of \( \leq n \)-dimensional definable sets over \( VF \), i.e. of definable subsets of \( n \)-dimensional varieties. Let \( VF[n] \) be the category of definable subsets \( X \subseteq VF^n \times RV^* \) such that the projection \( X \to VF^n \) has finite fibers. \( VF'[n] \) is the category of definable subsets \( X \subseteq V \times RV^* \), where \( V \) ranges over all \( VF(A) \)-definable sets of dimension \( n, m \in \mathbb{N} \), such that the projection \( X \to V \) is finite-to-one. \( VF, VF', VF'' \) are the unions over all \( n \). In all cases, the morphisms \( Mor(X,Y) \) are the definable functions \( X \to Y \).

**Lemma 8.1.** The natural inclusion of \( VF[n] \) in \( VF'[n] \) is an equivalence. If \( T \) is effective, so is the inclusion of \( VF''[n] \) in \( VF'[n] \).

**Proof.** We will omit the index \( \leq n \). The inclusion is fully faithful by definition, and we have to show that it hits every \( VF' \)-isomorphism type; in other words, that any definable \( X \subseteq (V \times RV^m) \) is definably isomorphic to some \( X' \subseteq VF^n \times RV^{m+l} \), for some \( l \) (with \( n = \dim(V) \)). Define isomorphisms can be glued on pieces, so we may assume \( V \) is affine, and admits a finite-to-one map \( h : V \to VF^m \). By Lemma 3.9, each fiber \( h^{-1}(a) \) is \( A(a) \)-definably isomorphic to some \( F(a) \subseteq RV^l \). By compactness, \( F \) can be chosen uniformly definable, \( F(a) = \{y \in RV^l : (a,y) \in F \} \) for some definable \( F \subseteq VF^n \times RV^l \); and there exists a definable isomorphism \( \beta : V \to F \), over \( VF^m \). Let \( \alpha(v,t) = (\beta(v),t), X' = \alpha(X) \).

Now assume \( T \) is effective. Let \( X \in \text{Ob}VF' \), \( X \subseteq V \times RV^m, V \subseteq VF^n \), such that the projection \( X \to V \) has finite fibers. Then by effectivity, for any \( v \in V \) (over any extension field), if \((v,c_1,\ldots,c_m) \in X \) then each \( c_i \), viewed as a ball, has a point defined over \( A(v) \). Hence the partial map \( V \times VF^m \to X, (v,z_1,\ldots,z_m) \mapsto (v,rv(z_1),\ldots,rv(z_m)) \) has an \( A \)-definable section; the image of this section is a subset \( S \) of \( V \times VF^m \), definably isomorphic to \( X \); and the Zariski closure \( V' \) of \( S \) in \( V \times VF^m \) has dimension \( \leq \dim(V) \).

The following definition and proposition apply both to the category of definable sets, and to the definable sets with volume forms.

**Definition 8.2.** \( X,Y \) are effectively isomorphic if

for any effective \( A \), \( X,Y \) are definably isomorphic in \( T_A \). If \( K_{\text{eff}}(VF) \) is the semi-ring of effective isomorphism classes of definable sets, \( K(VF) \) is the corresponding ring. Similarly \( K_{\text{eff}}(VF[n]) \), etc.

Over an effective base, in particular if \( T \) is effective over any field-generated base, effectively isomorphic is the same as isomorphic. But Example 4.7 shows that this is not so in general.

**Proposition 8.3.** Let \( T \) be \( V \)-minimal, or a finitely generated extension of a \( V \)-minimal theory. The following conditions are equivalent:

1. \([L^*X] = [L^*Y] \text{ in } K_+(RV[\leq n])]/I_{bp}[\leq n]
2. There exists a definable family \( \mathcal{F} \) of definable bijections \( X \to Y \), such that for any effective structure \( A, F(A) \neq \emptyset \).
3. \( X,Y \) are effectively isomorphic.
4. \( X,Y \) are definably isomorphic over any \( A \) such that \( VF^*(A) \to RV(A) \) is surjective.
5. For some finite \( A_0 \subseteq RV(<\emptyset>) \), \( X,Y \) are definably isomorphic over any \( A \) such that \( A_0 \subseteq rv(VF^*(A)) \).

**Proof.** (1) implies (5): By Proposition 6.1 (6.3 in the measured case), the given isomorphism \([L^*X] \to [L^*Y]\) lifts to an isomorphism \( LL^*X \to LL^*Y \); since \( T_A \supseteq ACVF_A \), this is also a \( T_A \) isomorphism; it can be composed with the isomorphisms \( X \to LL^*X, Y \to LL^*Y \).
(2) implies (3), (5) implies (4) implies (3) trivially.

(3) implies (1), (2): Let \( E_{\text{eff}} \) be as in Proposition 3.51. By (3), \( X, Y \) are \( E_{\text{eff}} \)-isomorphic. By Proposition 7.25, \([L^*X] = [L^*Y]\) in \( K_+(RV_{E_{\text{eff}}}[s]) / I_{sp}\). By \( RV(E_{\text{eff}}), \Gamma(E_{\text{eff}}) \subseteq \text{def}() \), so every \( E_{\text{eff}} \)-definable relation on \( RV \) is definable; i.e. \( RV_{E_{\text{eff}}}, RV \) are the same structure. So (1) holds.

Now by assumption, there exists an \( E_{\text{eff}} \)-definable bijection \( f : X \to Y \). \( f \) is an \( E_{\text{eff}} \)-definable element of a definable family \( \mathcal{F} \) of definable bijections \( X \to Y \). Since this family has an \( E_{\text{eff}} \)-point, and \( E_{\text{eff}} \) embeds into any effective \( B \), it has a \( B \) point too. Thus (3) implies (2).

\[ \square \]

### 8.2. Invariants of all definable maps

Let \([X] \) denote the class of \( X \) in \( K^\text{eff}_+(VF[n]) \).

**Proposition 8.4.** Let \( T \) be \( V \)-minimal. There exists a canonical isomorphism of Grothendieck semigroups

\[ \Psi : K^\text{eff}_+(VF[n]) \to K_+(RV[\leq n]) / I_{sp}[\leq n] \]

satisfying

\[ \Psi[X] = W/I_{sp}[\leq n] \iff [X] = [LW] \in K^\text{eff}_+(VF[n]) \]

**Proof.** Recall Definition 4.8. Given \( X = (X, f) \in \text{Ob} \ RV[k] \) we have \( LX \in \text{Ob} \ VF[k] \subseteq \text{Ob} \ VF[n] \). If \( X, X' \) are isomorphic, then by Proposition 6.1, \( LX, LX' \) are effectively isomorphic. Direct sums are clearly respected, so we have a semigroup homomorphism \( L : K_+(RV[\leq n]) \to K^\text{eff}_+(VF[n]) \). It is surjective by Proposition 4.5. By Proposition 8.3, the kernel is precisely \( I_{sp}[\leq n] \). Inverting, we obtain \( \Psi \).

\[ \square \]

**Definition 8.5.** Let \( K_+VF[n]/(\dim < n) \) be the Grothendieck ring of the category of definable subsets of \( n \)-dimensional varieties, and essential bijections between them. Let \( I_{sp}[n] \) be the congruence on \( RV[n] \) generated by pairs \( (X, X \times RV^{>0}) \) (where \( X \subseteq RV^* \) is definable, of dimension \( < n \).)

**Corollary 8.6.** \( \Psi \) induces an isomorphism \( K^\text{eff}_+(VF[n])/(\dim < n) \to RV[n]/I_{sp}[n] \)

**Corollary 8.7.** Let \( A, B \in RV[\leq n] \). Let \( n' > n \), and let \( A_N, B_N \) be their images in \( RV[\leq N] \). If \( (A_N, B_N) \in I_{sp}[\leq N] \) then \( (A, B) \in I_{sp}[\leq n] \).

**Proof.** By Proposition 8.4, \( (A, B) \in I_{sp}[\leq n] \) iff \( LA, LB \) are definably isomorphic; this latter condition does not depend on \( n \).

\[ \square \]

Putting Proposition 8.4 together for all \( n \) we obtain:

**Theorem 8.8.** Let \( T \) be \( V \)-minimal. There exists a canonical isomorphism of filtered semirings

\[ \Phi : K_+(VF) \to K_+(RV[\ast]) / I_{sp} \]

Let \([X] \) denote the class of \( X \) in \( K_+(VF) \). Then

\[ \Phi[X] = W/I_{sp} \iff [X] = [LW] \in K^\text{eff}_+(VF) \]

\[ \square \]

On the other hand, using the Grothendieck group isomorphisms of Proposition 8.4 and passing to the limit:
Corollary 8.9. Let $T$ be $V$-minimal. The isomorphisms of Proposition 8.4 inducing an isomorphism of Grothendieck groups:

$$
\int_{-\infty}^{K} : K^\text{eff}(VF[n]) \to K(RV[n])
$$

The isomorphism $f$ of Theorem 8.8 induces an injective ring homomorphism

$$
\int_{-\infty}^{K} : K^\text{eff}(VF) \to K(RV)[J^{-1}]
$$

where $J = \{1\} - [\text{RV}^>0]_1 \in K(RV)$.

Proof. We may work over an effective base. With subtraction allowed, the generating relation of $I_{sp}$ can be read as: $[\{1\}] = [\{1\} - [\text{RV}^>0]_1 := J$; so that the groupification of $K_+(RV[\leq n])/I_{sp}[\leq n]$ is isomorphic to $K(RV[n])$, via the embedding of $K_+(RV[n])$ as a direct factor in $K_+(RV[\leq n])$. Thus the groupification of the homomorphism of Theorem 8.8 is a homomorphism

$$
\int_{-\infty}^{K} : K(VF) \to \lim_{n \to \infty} K(RV[n])
$$

where the direct limit system maps are given by $[X]_d \mapsto ([X]_{d+1} - ([X]_d \times (\text{RV}^>0))) = [X]_d J$. This direct limit embeds into $K(RV)[J^{-1}]$ by mapping $X \in K(RV[n])$ to $XJ^{-n}$. \hfill \square

8.3. Definable volume forms: VF. We will now define the category $\mu VF[n]$ of $n$-dimensional $T_A$-definable sets with definable volume forms, up to RV- equivalence and the same up to $\Gamma$-equivalence. We will represent the forms as functions to RV, that transform in the way volume forms do.

By way of motivation: in a local field with an absolute value, a top differential form $\omega$ induces a measure $|dw|$. For a regular isomorphism $f : V \to V'$ have $\omega = h^*\omega'$ for a unique $h$, and $f$ is measure preserving between $V, |\omega|$ and $(V', |\omega'|)$ iff $|h| = 1$.

We do not work with an absolute value into the reals, but instead define the analogue using the map rv or, a coarser version, the map val into $\Gamma$. When $\Gamma = Z$, the latter is the is the usual practice in Denef-style motivic integration. Using rv leaves room for considering an absolute value on the residue field, and iterating the integration functorially when places are composed, for instance $C((x))(y) \to C((x)) \to \mathbb{C}$. This functoriality will be described in a sequel.

In the definition below, the words “almost every $y \in Y$” will mean: for all $y$ outside a set of $\text{VF}$-dimension $< \text{dim}_V(Y)$.

Definition 8.10. Ob $\mu VF[n, -]$ consists of pairs $(Y, \omega)$, where $Y$ is a definable subset of $VF^n \times RV^*$, and $\omega : Y \to RV$ is a definable map. A morphism $(Y, \omega) \to (Y', \omega')$ is a definable essential bijection $F$ such that for almost every $y \in Y$,

$$
\omega(y) = \omega'(F(y)) \cdot \text{rv}(\text{Jcb}F(y))
$$

(We will say: “$F : (Y, \omega) \to (Y', \omega')$ is measure preserving.”)

$\mu_1 VF[n, -]$ is the category of pairs $(Y, \omega)$ with $\omega : Y \to \Gamma$ a definable function. A morphism $(Y, \omega) \to (Y', \omega')$ is a definable essential bijection $F : Y \to Y'$ such that for almost every $y \in Y$,

$$
\omega(y) = \omega'(F(y)) + \text{val}(\text{Jcb}F(y))
$$

(“$F : (Y, \omega) \to (Y', \omega')$ is $\Gamma$-measure preserving.”)

$\mu VF[n], \mu_1 VF[n]$ are the full subcategories of $\mu VF[n, -], \mu_1 VF[n, -]$ (respectively) whose objects admit a finite-to-one map to $VF^n$. 
In this definition, let \( t_1(y), \ldots, t_n(y) \) be the VF-coordinates of \( y \in Y \). One can think of the form as \( \omega(y)dt_1 \cdots dt_n \).

Note that \( \text{VF}_{\text{vol}} \) of Definition 5.19 is isomorphic to the full subcategory of \( \mu \text{VF} \) whose objects are pairs \((Y,1)\).

**Remark 8.11.** When \( T \) is \( V \)-minimal and effective, the data \( \omega \) of an object \((Y,\omega)\) of \( \mu\text{VF}[n] \) can be written as \( rv \circ \Phi \) for some \( \Phi : Y \to \text{VF} \). (Write \( \omega = \tilde{\omega} \circ F \circ F \) for some \( F \), and use Proposition 6.1 to lift \( \tilde{\omega} \) to some \( G \), so that \( \omega = rv \circ G \circ F \).) It is thus possible to view \( \omega \) as the \( \Gamma \)-image (resp. \( \Gamma \)-image) of a definable volume form on \( Y \). One could equivalently take \( \omega \) to be a definable section of \( \Lambda^nTY/(1+M) \), where \( TY \) is the (appropriately defined) tangent bundle, \( \Lambda^n \) the \( n \)-th exterior power with \( n = \dim(Y) \).

For \( \text{VF}_T \) the category we take is slightly more flexible than taking varieties with absolute values of volume forms, even if \( T \) is \( V \)-minimal and effective, in that expressions such as \( \int |\sqrt{z}| \, dx \) are allowed.

In either of these categories, one could restrict the objects to bounded ones:

**Definition 8.12.** Let \( \mu\text{VF}_{\text{bdd}}[n] \) be the full subcategory of \( \mu\text{VF}[n] \) whose objects are bounded definable sets, with bounded definable forms \( \omega \). Similarly one defines \( \mu\text{VF}_T_{\text{bdd}} \).

Here bounded means that there is a lower bound on the valuation of any coordinate of any element of the set. A similar definition applies in \( \text{RV} \) and \( \mu\text{RV} \).

Note that if an object of \( \mu\text{VF}[n] \) is \( \mu\text{VF}[n] \)-isomorphic to an object of \( \mu\text{VF}_{\text{bdd}}[n] \), it must lie in \( \mu\text{VF}_{\text{bdd}}[n] \).

### 8.4. Definable volume forms: RV

We will define a category \( \mu\text{RV}[n] \) of definable subsets of \( \text{RV}^n \), with additional data that can be viewed as a volume form. Unlike \( \mu\text{VF}[n] \), in \( \mu\text{RV}[n] \) subsets of dimension \( < n \) are not ignored: a point of \( \text{RV}^n \) corresponds to an open polydisc of \( \text{VF}^n \), with nonzero \( n \)-dimensional volume.

In particular, the Jacobian of a morphism needs to be defined at every point, not just away from a smaller-dimensional set. However, in accord with Lemma 6.3, it may be modified by \( k^* \)-multiplication on a smaller-dimensional set.

**Definition 8.13.** The objects of \( \mu\text{RV}[n] \) are definable triples \( (X,f,\omega) \), \( X \subseteq \text{RV}^{n+m} \), \( f : X \to \text{RV}^n \) finite-to-one, and \( \omega : X \to \text{RV} \).

We define a multiplication \( \mu\text{RV}[n] \times \mu\text{RV}[n'] \to \mu\text{RV}[n+n'] \) by \( (X,f,\omega) \times (X',f',\omega') = (X \times X', f \times f', \omega \cdot \omega') \). Here \( \omega \cdot \omega' = \omega(x)\omega'(x') \).

Given \( X = (X,f,\omega) \), we define an object \( LX \) of \( \text{VF}[n] \); namely \( (LX,Lf,L\omega) \) where \( LX = X \times frv(\text{VF}^n) \), \( Lf(a,b) = f(a,rv(b)) \), \( L\omega(a,b) = \omega(a,rv(b)) \). (Sometimes we will write \( f,\omega \) for \( Lf,L\omega \).)

A morphism \( \alpha : X = (X,f,\omega) \to X' = (X',f',\omega') \) is a definable bijection \( \alpha : X \to X' \), such that

\[
\omega(y) = \omega'(\alpha(y)) \cdot rv(\text{jcb}_{\text{RV}}(\alpha)(y))
\]

for almost all \( y \).

where “almost all” means: away from a set \( Y \) with \( \dim_{\text{RV}}(f(Y)) < n \); and

\[
\text{val}_{rv}\omega(y) + \sum_{i=1}^{n} \text{val}_{rv}f_i(y) = \text{val}_{rv}\omega'(\alpha(y)) + \sum_{i=1}^{n} \text{val}_{rv}f'_i(\alpha(y))
\]

for all \( y \).

The objects of \( \mu\text{RV}_T[n] \) are triples \( (X,f,\omega) \), with \( f : X \to \text{RV}^n \), \( \omega : X \to T \). A morphism \( \alpha : (X,f,\omega) \to (X',f',\omega') \) is a definable bijection \( \alpha : X \to X' \) such that \( \text{val}_{rv}\omega(y) + \sum_{i=1}^{n} \text{val}_{rv}f_i(y) = \text{val}_{rv}\omega'(\alpha(y)) + \sum_{i=1}^{n} \text{val}_{rv}f'_i(\alpha(y)) \) for all \( y \). Disjoint sums and products are defined as for \( \mu\text{RV} \).

\( \mu\text{RES}[n] \) is the full subcategory of \( \mu\text{RV}[n] \) with objects \( (X,f,\omega) \), such that \( \text{val}_{rv}(X) \) is finite. In this case, \( \omega \) takes finitely many values too.
$K^\text{eff}_+ \text{RV}[n]$ is the Grothendieck semigroup of $\mu \text{RV}[n]$ with respect to effective isomorphism. $K^\text{eff}_+ \mu \text{RV}$ is the direct sum $\oplus_n K^\text{eff}_+ \mu \text{RV}[n]$; it clearly inherits a semiring structure from Cartesian multiplication, $(X, f, \omega) \times (X', f', \omega') = (X \times X', (f \times f'), \omega \cdot \omega')$.

The morphisms of $\mu \text{RV}[n]$ are called $\Gamma$- measure preserving.

The category $\text{RV}_{\text{vol}}[n, -]$ of Definition 5.21 is isomorphic to the full subcategory whose objects have $\omega = 1$.

**Remark** The semiring $K^\text{eff}_+ \text{RV}_{\text{vol}}$ is naturally a subsemiring of $K^\text{eff}_+ \mu \text{RV}$. The latter is obtained by inverting $\{(a)_n\}$ for $a \in \text{RV}$ and taking the 0th graded component. This process is needed in order to identify integrals of functions in $n$ variables with volumes in $n + 1$ variables. Thus as semirings they are closely related. But if the dimension grading is taken into account, the subsemiring of $\text{RV}$-volumes contains finer information connected to integrability of forms.

8.5. **The kernel of $L$ in the measured case.** The description of the kernel of $L$ on the semigroup of definable sets with volume forms is essentially the same as for definable sets. We will now run through the proof, indicating the modifications. The principal change is the introduction of a category with fewer morphisms, defined not only with reference to $\text{RV}$ but also to $\text{VF}$. For effective bases, the category is identical to $\mu \text{RV}$, so it will be invisible in the statements of the main theorems; but during the induction in the proof, bases will not in general be effective and the mixed category introduced here has better properties.

Both the introduction of the various intermediate categories and the repetition of the proof would be unnecessary if we had a positive answer to Question 7.9. In this case the proof of Lemma 8.23 would immediately lift to higher dimensions. Indeed the characterization of the kernel of the map $L$ on Grothendieck groups would be uniformized not only for the categories we consider, but for a range of categories carrying more structure.

The integer $n$ will be fixed in this subsection.

**Lemma 8.14.** Let $(X, \omega) \in \text{Ob} \mu \text{VF}[n, -], Y \in \text{Ob} \text{VF}[n, -]$, and let $F : Y \to X$ be a definable bijection.

1. There exists $\psi : Y \to \text{RV}$ such that $F : (Y, \psi) \to (X, \omega)$ is measure preserving.
2. $\psi$ is essentially unique in the sense that if $\psi'$ meets the same condition, then $\psi, \psi'$ are equal away from a subset of $X$ of smaller dimension.
3. Dually, given $F, X, Y, \psi$ there exists an essentially unique $\omega$ such that $F : (Y, \psi) \to (X, \omega)$ is measure preserving.
4. Lemma 7.11 applies to $\mu \text{VF}[n, -]$ and to $\mu \text{VF}[n]$

**Proof.** (1,2) Let $\psi(y) = \omega(\alpha(y)) \cdot \text{rv}(J \text{cb}_n(\alpha)(y))$. By definition of $\mu \text{VF}$ this works, and is the only choice “almost everywhere”. (3) follows from the case of $F^{-1}$. (4) Now let $X, Y \in \text{Ob} \mu \text{VF}[n]$ and let $F \in \text{Mor} \mu \text{VF}[n](X, Y)$. We have $X = (X, \omega_X), Y = (Y, \omega_Y)$ for some $X, Y \in \text{Ob} \text{VF}[n]$ and $\omega_X : X \to \text{RV}, \omega_Y : Y \to \text{RV}$. By Lemma 7.11 there exist $X = X_1, \ldots, X_n = Y \in \text{Ob} \text{VF}[n]$ and essentially unary $F_i : X_i \to X_{i+1}$ with $F = F_{n-1} \circ \cdots \circ F_1$. Let $\omega_1 = \omega_X$, and inductively let $\omega_{i+1}$ be such that $F_i \in \text{Mor} \mu \text{VF}[n](\langle X_i, \omega_i \rangle, \langle X_{i+1}, \omega_{i+1} \rangle)$. Then $F \in \text{Mor} \mu \text{VF}[n](\langle X, \omega \rangle, \langle Y, \omega_n \rangle)$. By the uniqueness it follows that $\omega_Y, \omega_n$ are essentially equal. \qed

**Definition 8.15.** Given $X, Y \in \text{Ob} \mu \text{RV}[n, -]$ call a definable bijection $h : X \to Y$ liftable if there exists $F \in \text{Mor} \mu \text{VF}[n](X, Y)$ with $\rho_Y F = h \rho_X$.

Let $C = \mu \text{RV}[n, -]$ be the subcategory of $\mu \text{RV}[n, -]$ consisting of all objects and liftable morphisms.

By Proposition 5.22, liftable morphisms must preserve the volume forms, so $C$ is a subcategory of $\mu \text{RV}[n, -]$.
Over an effective base, $\mathcal{C} = \muRV[n, -]$ (Lemma 6.3), and the condition of existence of $s$ in Definition 8.16 (1) below is equivalent to: \( f_n(y) \in \text{acl}(f_1(y), \ldots, f_{n-1}(y)) \).

**Definition 8.16.** (1) Let $Y = (Y, f, \omega) \in \text{Ob} \, \muRV[n, -]$ be such that there exists $s : Y \times f_1, \ldots, f_{n-1}, \text{VF}^{n-1} \to \text{VF}$ with $\text{rv}(s(y, u_1, \ldots, u_{n-1})) = f_n(y)$. Let $Y' = Y \times \text{RV}^{>0}$.

For $(y, t) \in Y'$, define $f'_i = (f'_1, \ldots, f'_{n})$ by: $f'_i(y, t) = f_i(y)$ for $i < n$, $f'_n(y, t) = tf_n(y)$.

Let $\omega'(y, t) = \omega(y)$. Then $\tilde{Y} = (Y', f', \omega')$ is an elementary blowup of $Y$. It comes with the projection map $Y' \to Y$.

(2) Let $X = (X, g, \omega) \in \text{Ob} \, \muRV[n, -]$, $X' = X' \cup X''$, $g' = g|X'$, $g'' = g|X''$, $\omega' = \omega|X'$, $\omega'' = \omega|X''$, and let $\phi : Y \to (X', g', \omega')$ be a $\muRV[n, -]$-isomorphism. Then the RV-blowup $\tilde{X}_0$ is defined to be $\tilde{Y} + (X'', g'', \omega'') = (Y' \cup X'', f' \cup g', \omega' \cup \omega'')$. It comes with $b : Y' \cup X'' \to X$, defined to be the identity on $X''$, and the projection on $Y'$. $X'$ is called the blowup locus of $b : \tilde{X}_0 \to X$.

An iterated RV-blowup is obtained by finitely many iterations of RV-blowups.

**Definition 8.17.** Let $\mu_{\text{sp}}[n]$ be the set of pairs $(X_1, X_2) \in \text{Ob} \, \muRV[n, -]$ such that there exist iterated blowups $b_i : X_i \to X_i$ and a $\muRV[n, -]$-isomorphism $F : X_1 \to X_2$.

When $n$ is fixed, we will simply write $\mu_{\text{sp}}$. On the other hand we will need to make explicit the dependence on the theory; we write $\mu_{\text{sp}}(A)$ for the congruence $\mu_{\text{sp}}$ of the theory $\text{T}_A$.

When $X = (X, f, \omega) \in \text{Ob} \, \muRV[n, -]$, $h : X \to W$ is a definable map, and $c \in W$, define $X_c = (h^{-1}(c), f| h^{-1}(c), \omega| h^{-1}(c))$.

Let $X_1, X_2 \in \text{Ob} \, \muRV[n, -]$, and let $f_i : X_i \to Y$ be a definable map, with $Y \subseteq \text{RV}^*$. In this situation the existence of $\mu_{\text{sp}}[n, -]$ isomorphisms between each pair of fibers $X_1(a), X_2(a) (a \in Y)$ does not necessarily imply $X_1 \simeq_{\text{RV}^*[\leq n, -]} X_2$, because of the explicit reference to dimension in the definition of morphisms; the dimension of the allowed exceptional sets may accumulate over $Y$. The definition of morphisms for $\muVF[n]$ also allows a smaller dimensional exceptional set; but this does not create a problem when fibered over $W \subseteq \text{RV}^*$, since by Lemma 3.66 $\max_{Z \in W} \dimVF(Z) = \dimVF(Z)$. Thus an RV-disjoint union of $\muVF[n]$-isomorphisms is again a $\muVF[n]$-isomorphism, and it follows that the same is true for $\muRV[n, -]$. We thus have:

**Lemma 8.18.** Let $X = (X, f, \omega), X' = (X', f', \omega) \in \muRV[n, -]$, and let $h : X \to W \subseteq \text{RV}^*, h' : X' \to W$ be definable maps. If for each $c \in W$, $(X_c, X'_c) \subseteq \mu_{\text{sp}}(<c>)$ then $(X, X') \subseteq \mu_{\text{sp}}$.

**Proof.** Lemma 2.3 applies to $\text{RV}_{\text{sp}}$-isomorphisms, and hence using Remark 7.13 also to blowups. It also applies to $\muRV[n, -]$-isomorphisms by the discussion above, and hence to $\mu_{\text{sp}}$-equivalence. \(\square\)

In other words, there exists a well-defined direct sum operation on $\muRV[n, -]/\mu_{\text{sp}}$, with respect to RV-indexed systems.

**Lemma 8.19.** (1) Let $Y'$ be an elementary blowup of $Y$. $Y'$ is $\text{C}$-isomorphic to $Y'' = (Y'', f'', \omega')$, with

$$Y'' = \{(y, t) \in Y \times \text{RV}_\infty : \text{val}_\text{rv}(t) > f_n(y)\}$$

$$f''(y, t) = (f_1(y), \ldots, f_{n-1}(y), t), \omega'(y, t) = \omega(y)$$

(3) Up to isomorphism, the blowup depends only on blowup locus. In other words if $X, X', g', \omega', \omega'$ are as in Definition 8.16, and $\phi_i : Y_i \to (X', g', \omega')$ ($i = 1, 2$) are $\muRV[n, -]$-isomorphisms, then $X_{\phi_1}, X_{\phi_2}$ are $X$-isomorphic in $\muRV[n, -]$.

**Proof.** (1) The isomorphism is given by $h((y, t)) = (y, tf_n(y))$; since $f_n$ always lifts to a function $F_n : \text{LV} \to \text{VF}$ (a coordinate projection), $h$ can be lifted to $H$ defined by $H((y, t)) = (y, tF_n(y))$.
By assumption, \( \phi_1, \phi_2 \) lift to measure preserving maps \( \Phi_i : LY_i \to LX' \). On the other hand, by the assumption on existence of a section \( s \) of \( f_n \), we have measure preserving isomorphisms \( \alpha_1 : LY_1 \to Y_1, (y, u_1, \ldots, u_n) \mapsto (y, u_1, \ldots, u_{n-1}, (u_n - s)/s) \). Similarly we have \( \alpha_2 : LY_2 \to Y_2 \). Composing we obtain \( \alpha \Phi_2^{-1} \Phi_1^{-1} : L\hat{Y}_1 \to L\hat{Y}_2 \); it is easy to check that this is \( \sim \)-invariant and shows that \( L\hat{Y}_1, L\hat{Y}_2 \) are \( Y \)-isomorphic in \( \mu \text{RV}[n, \cdot] \). Taking disjoint sum with the complement \( X'' \) of \( X' \) we obtain the result.

**Remark** There is also a parallel of Lemma 7.15: Let \( Y = (Y, g) \in \text{Ob RV}_{\infty}[n, \cdot] \), with \( \text{dim}(g(Y)) < n \); let \( f : Y \to \text{RV}^{n-1} \) be isogenous to \( g \). Let \( h : Y \to \text{RV} \) be definable, with \( h(y) = \text{acl}(g(y)) \) for \( y \in Y \), and with \( \sum(g) = \sum(f) + \text{val}_v(h) \). Let \( Y' = Y \times \text{RV}_{\infty}^{\geq 0} \), and \( f'(y, t) = (f(y), th(y)) \). Then for appropriate \( \omega', Y' = (Y', f', \omega') \) with the projection map to \( Y \) is a blowup. This follows from Lemma 7.15, and Lemma 8.14 (3).

**Notation** For \( X \in \text{RV}[n, \cdot] \), \( [X] = [(X, 1)] \) denotes the corresponding object of \( \mu \text{RV}[n, \cdot] \) with form 1.

**Lemma 8.20.** Lemma 7.18 (1-5) holds for \( \mu \text{RV}[n, \cdot] \). We also have:

(6) As a semi-ring congruence on \( K_+ \mu \text{RV}[n, \cdot], \mu_{\text{sp}} \) is generated by \( \{[[1]], [[\text{RV}_{\infty}]^0]_1] \) (with the forms 1)

**Proof.** (1)-(5) go through with the same proof. For (6), let \( \sim \) be the congruence generated by this element. By blowing up a point one sees immediately that \( \{[[1]], [[\text{RV}_{\infty}]^0]_1] \in \mu_{\text{sp}} \), so \( \sim \subseteq \mu_{\text{sp}} \). For the converse direction we have to show that \( (\hat{Y}, Y, \sim) \) whenever \( Y \) is a blowup of \( Y \); the elementary case suffices, since the \( \mu \text{RV}[n, \cdot] \)-isomorphisms of Definition 8.16 (2) are already accounted for in the semigroup \( K_+ \mu \text{RV}[n, \cdot] \). Now \( Y = (Y, f, \omega) \) with \( f_n(y) \in \text{RV} \). Since \( \text{dim}(Y') < n \), we have \( Y \simeq (Y', f', \omega') \) where \( f'_i = f_i \) for \( i < n \), \( f'_n = 1 \), and \( \omega' = f_n \omega \). So we may assume \( f_n = 1 \). In this case, as in the proof of Lemma 7.18 (6), \( (\hat{Y}, Y) \in \sim \)

**Definition 8.21.** Let \( J \) be a \( k \)-element set of natural numbers. \( \text{VFR}_\mu[J, J, \cdot] \) is the set of triples \( X = (X, f, \omega) \), with \( X \subseteq \text{VF}^J \times \text{RV}^*, f : X \to \text{RV}^*_\infty, \omega : X \to \text{RV}, \) and such that \( f \) and \( \omega \) factor through the projection \( \text{pr}_{\text{RV}}(X) \) of \( X \) to the RV-coordinates. \( \mu_{\text{sp}} \) is the equivalence relation on \( \text{VFR}_\mu[J, J, \cdot] \):

\[
(X, Y) \in \mu_{\text{sp}} \iff (X_a, Y_a) \in \mu_{\text{sp}}(a > a) \text{ for each } a \in \text{VF}^J
\]

\( K_+ \text{VFR}_\mu \) is the set of equivalence classes.

For \( j \in J \), let \( \pi^J : \text{VF}^k \times \text{RV}^* \to \text{VF}^{J-\{j\}} \times \text{RV}^* \) be the projection forgetting the \( j \)-th VF coordinate. We will write \( \text{VFR}_\mu[k, J, \cdot], \text{VF}^k, \text{VF}^{k-1} \) for \( \text{VFR}_\mu[J, J, \cdot] \), \( \text{VF}^J, \text{VF}^{J-\{j\}} \) respectively when the identity of the indices is not important.

The map \( L : \text{Ob} \mu \text{RV}[n, \cdot] \to \text{Ob} \mu \text{VF}[n] \) induces, by Lemma 6.3, a homomorphism \( L : K_+ \mu \text{RV}[n, \cdot] \to K_+ \mu \text{VF}[n] \). By Proposition 4.5 it is surjective.

**Lemma 8.22.** Let \( X, X' \in \mu \text{RV}[n, \cdot] \), and let \( G : LX' \to LX \) be a special bijection. Then \( X' \) is isomorphic to an iterated blowup of \( X \).

**Proof.** Clear from Lemma 7.19, since strong isomorphisms are also \( \mu \text{RV}[n, \cdot] \)-isomorphisms.

**Lemma 8.23.** The homomorphism \( L : K_+ \mu \text{RV}[1, \cdot] \to K_+ \mu \text{VF}[1, \cdot] \) is surjective, with kernel equal to \( \mu_{\text{sp}}[1] \). The image of \( K_+ \text{RV}_{\text{vol}}[1, \cdot] \) is \( K_+ \text{VF}_{\text{vol}}[1, \cdot] \)

**Proof.** Let \( X, Y \in \mu \text{RV}[1, \cdot] \), and let \( F : LX \to LY \) be a definable measure preserving bijection. We have \( X = (X, f, \omega), Y = (Y, g, \omega) \) with \( (X, f), (Y, g) \in \text{RV}[1, \cdot] \). By Lemma 7.6 there exist special bijections \( b_X : LX \to LX, b_Y : LY' \to LY \) and an \( \sim \)-invariant definable bijection
$F' : LX' \to LY'$ such that $byF' = FbX$. We used here that any $\sim$-invariant object can be written as $LX'$ for some $X'$. Since $F,bX,bY$ are measure preserving bijections, so is $F'$. By Lemma 8.22, $X' \to X$ and $Y' \to Y$ are blowups; and $F'$ descends to a definable bijection between them. This bijection is measure preserving by Lemma 5.22. Hence by definition $(X,Y) \in \mu_{I_{sp}}$. □

By Proposition 8.23, the inverse of $L : RV[1,.] \to VF[1,.]$ induces an isomorphism $I_{1}^{col} : K_{+}VF_{vol}[1,.] \to K_{+}RV_{vol}[1,.] / \mu_{I_{sp}}$.

\[ I_{1}^{col}([X]) = [Y] / \mu_{I_{sp}} \iff [LY] = [X] \]

Let $X = (X,f,\omega) \in VF_{vol}[k,l,\cdot]$. By assumption, $f,\omega$ factor through $\pi^{d}$, so that they can be viewed as functions on $\pi^{d} X$. We view the image $(\pi^{d} X, f, \omega)$ as an element of $VF_{\psi}[k-1,l,\cdot]$. Each fiber of $\pi^{d}$ is a subset of $VF$; it can be viewed as an element of $VF_{\psi}[1] \subseteq \mu VF[1] \subseteq \mu VF[1,\cdot]$.

Claim Relative $\mu_{I_{sp}}$-equivalence implies $\mu_{I_{sp}}$-equivalence, in the following sense. Let $X_i \subseteq RV^* (i = 1,2); h_i : X_i \to W \subseteq RV^*; f_W : W \to RV^j, \omega : W \to RV$, and $f_j : X \to RV^k$ be definable sets and functions. Let $X_i = (X_i, (f_{W} \circ h_i), f_j \circ h_i)$. Let $X_i(w) = (X_i(w), f_i X_i(w), \omega \circ h_i X_i(w))$ where $X_i(w) = h_i^{-1}(w)$. If $X_1(w), X_2(w) \in I_{sp}(< w >)$ for each $w \in W$, then $(X_1, X_2) \in \mu_{I_{sp}}$.

The Claim allows us to relativize $I_{1}^{col}$ to $\pi^{d}$. We obtain a map

\[ I^{j} = I_{k,l}^{j} : VF_{\psi}[k,l,\cdot] \to K_{+}VF_{\psi}[k-1,l+1,] / \mu_{I_{sp}} \]

Lemma 8.24. Let $X = (X,f,\omega), X' = (X',f',\omega') \in VF_{\psi}[k,l,\cdot]$.

1. $I^{j}$ commutes with maps into RV: if $h : X \to W \subseteq RV^*$ is definable, $X_c = h^{-1}(c)$, then $I^{j}(X) = \sum_{c \in W} I^{j}(X_c)$.

2. If $([X],[X']) \in \mu_{I_{sp}}$ then $(I^{j}(X), I^{j}(X')) \in \mu_{I_{sp}}$.

3. $I^{j}$ induces a map $K_{+}VF_{\psi}[k,l,\cdot] / \mu_{I_{sp}} \to K_{+}VF_{\psi}[k-1,l+1,\cdot] / \mu_{I_{sp}}$.

Proof. (1) This reduces to the case of $I_{1}^{col}$, where it is an immediate consequence of the uniqueness, and the fact that $L$ commutes with maps into RV in the same sense.

(2) All equivalences here are relative to the $k-1$ coordinates of VF other than $j$, so we may assume $k = 1$, and write $I$ for $I^{j}$.

For $a \in VF$, $([X_a],[X'_a]) \in \mu_{I_{sp}}(< a >)$. By stable embeddedness of RV, there exists $\alpha = \alpha(a) \in RV^*$ such that $X_{\alpha}, X'_{\alpha}$ are $< \alpha$-definable there are $< \alpha$-definable blowups $\tilde{X}_a, \tilde{X}'_a$ and an $< \alpha$-definable isomorphism between them, lifting to an $a$-definable isomorphism. Using (1) and Lemma 8.18 we may assume that $\alpha$ is constant. So for some $W \in Ob VF[1], Y,Y' \in \mu RV[l+1,\cdot]$, we have $X = W \times Y, X' = W \times Y'$, $Y, Y'$ are blowups of $Y, Y'$ respectively, $\phi : Y \to Y'$ is a bijection, and for any $w \in W$ there exists a measure preserving $F_w : LY \to LY$ lifting $\phi$. Then $I(X) = I(W) \times Y, I(X') = I(W) \times Y'$ and the bijection $Id_{I(W) \times \phi}$ is lifted by the measure preserving bijection $(w,y) \mapsto (w,F_w(y))$.

(3) by (2). □

Lemma 8.25. Let $X = (X,f,\omega) \in Ob VF_{\psi}[J,l,\cdot]$. If $j \neq j' \in J$ then $I^{j}I^{j'} = I^{j}I' : K_{+}VF_{\psi}[J,l,\cdot] / \mu_{I_{sp}} \to K_{+}VF_{\psi}[J \setminus \{j,j'\},l+2,\cdot] / \mu_{I_{sp}}$.
Proof. We may assume $S = \{1, 2\}, j = 1, j' = 2$, since all is relative to $VF^S(\cup_{j, j'})$. By Lemma 7.23 (1) and Lemma 8.18 it suffices to prove the statement for each fiber of a given map into $RV[1]$. Hence we may assume $X \subseteq VF^2$ so that $f$ is constant; and by Lemma 5.10, we can assume $X$ is a basic 2-cell:

$$X = \{ (x, y) : x \in X_1, rv(y - G(x)) = \alpha_1 \} \quad X_1 = rv^{-1}(\delta_1) + c_1$$

The case where $G$ is constant is easy, since then $X$ is a finite union of rectangles. Otherwise $G$ is invertible, and by niceness of $G$ we can also write:

$$X = \{ (x, y) : y \in X_2, rv(x - G^{-1}(y)) = \beta \}, \quad X_2 = rv^{-1}(\delta_2) + c_2$$

We immediately compute:

$$I_2 I_1(X) = (\delta_1, \alpha_1), \quad I_1 I_2(X) = (\alpha_2, \delta_2)$$

and necessarily $val_{\nu} \delta_1 + val_{\nu} \alpha_1 = val_{\nu} \alpha_2 + val_{\nu} \delta_2$. (Lemma 5.4). We have bijections $F_j : X \to LF_j(X)$. The map $F_1 F_2 F_1^{-1} F_2^{-1} : L I_2 I_1(X) \to L I_1 I_2(X)$ lifts the unique bijection between the singleton sets $\{ (\delta_1, \alpha_1) \}, \{ (\alpha_2, \delta_2) \}$, and shows that $[\delta_1, \alpha_1)_2 = [\alpha_2, \delta_2)_2$. \hfill $\Box$

Proposition 8.26. Let $X, Y \in \mu RV[\leq n, \cdot]$. If $L X, L Y$ are isomorphic, then $([X], [Y]) \in I_{ap}$.

Proof. Identical to the proof of Proposition 7.25, only quoting Lemma 8.25 in place of Lemma 7.24, and Lemma 8.14 to enable using Lemma 7.11. \hfill $\Box$

Proposition 8.27. Proposition 8.3 is valid for $\mu VF[n], \mu RV[n], \mu I_{ap}[n]$.

Proof. Same as the proof of Proposition 8.3, but using Proposition 6.3 in place of 6.1 and Proposition 8.26 in place of 7.25. \hfill $\Box$

8.6. Invariants of measure preserving maps, and some induced isomorphisms.

Theorem 8.28. Let $T$ be $V$-minimal. There exists a canonical isomorphism of Grothendieck semigroups

$$\int : K^@_+ (\mu VF[n, \cdot]) \to K_+ (\mu RV[n, \cdot])/\mu I_{ap}[n]$$

Let $[X]$ denote the class of $X$ in $K^@_+ (\mu VF[n])$. Then

$$\int [X] = W/\mu I_{ap}[n] \iff [X] = [LW] \in K^@_+ (\mu VF[n])$$

Proof. Given $X = (X, f, \omega) \in Ob \mu RV[n]$ we have $L X \in Ob \mu VF[n]$.

If $X, X'$ are isomorphic, then by Lemma 6.3, $L X, L X'$ are effectively isomorphic.

Direct sums are clearly respected, so we have a semigroup homomorphism $L : K_+ (\mu RV[n]) \to K^@_+ (\mu VF[n])$.

It is surjective by Proposition 4.5, injective by Proposition 8.3.

Inverting, we obtain $I$. \hfill $\Box$

Let $\mu_{I_{ap}}'$ be the semigroup congruence on $RV_{vol}[n]$ generated by $((Y, f), (Y \times RV^{>0}, f'))$ where $Y, f, f'$ are as in Definition 7.12. Let $\mu_{I_{ap}}$ be the congruence on $K_+ \mu_T RV[n]$ generated by $([1_1], [1_1][RV^{>0}])$, with the constant $\Gamma$-form $0 \in \Gamma$.

Assume given a distinguished subgroup $N_1$ of the multiplicative group of the residue field $k$. For example, $N_1$ may be the group of elements of norm one, with respect to some absolute value $| \cdot |$ on $k$. With this example in mind, write $|x| = 1$ for $x \in N_1$. Let $|\mu|VF[n]$ be the subcategory of $VF[n]$ with the same objects, and such that $F \in Mor_{|\mu|VF[n]}$ iff $F \in Mor_{\mu, VF[n]}$ and $|JRV(F)| = 1$ almost everywhere. Similarly define $|\mu|RV[n]$.
Theorem 8.29. The isomorphism $\int$ of Theorem 8.28 induces isomorphisms:

$$
\begin{align*}
(9) & \quad K^\text{eff}_+ VF_{\text{vol}}[n] \to K_+ RV_{\text{vol}}[n] / \mu_{\text{sp}}[n] \\
(10) & \quad K^\text{eff}_+ VF_{\text{vol}}^{\text{bdd}}[n] \to K_+ RV_{\text{vol}}^{\text{bdd}}[n] / \mu_{\text{sp}}[n] \\
(11) & \quad K^\text{eff}_+ \mu V F_{\text{vol}}^{\text{bdd}}[n] \to K_+ \mu RV^{\text{bdd}}[n] / \mu_{\text{sp}}[n] \\
(12) & \quad K^\text{eff}_+ [\mu] VF[n] \to K_+ [\mu] RV[n] / \mu_{\text{sp}}[n] \\
(13) & \quad K^\text{eff}_+ [\mu_1] VF[n] \to K_+ [\mu_1] RV[n] / \mu_{\text{sp}}[n] \\
\end{align*}
$$

Proof. Since Proposition 4.5 uses measure preserving maps, Proposition 6.1 do not go out of the subcategory $VF_{\text{vol}}$, and $RV_{\text{vol}}[n]$ is a full subcategory of $\mu RV[n]$, we have (9). It is similarly easy to see that “dimension $< n$” and boundedness are preserved, hence (10), (11).

We have $K^\text{eff}_+[\mu] VF = K^\text{eff}_+[\mu] VF / N_{VF}$, where $N_{VF} \equiv \{([X, \omega], [X, g \omega]) : g : X \to RV, |g| = 1\}$. Similarly for $K^\text{eff}_+[\mu] RV$. Thus for (12) it suffices to show that $(\int (X), \int (Y)) \in N_{RV} \iff (X, Y) \in N_{VF}$. For $X \in \text{Ob} \mu VF[n]$ or $X \in \text{Ob} \mu RV[n]$ with $RV$-volume form $\omega$, given $g : X \to RV$, let $\# X$ denote the same object but with volume form $g \omega$. In one direction we have to show: $(LX, LY) \in N_{VF}$ if $(X, Y) \in N_{RV}$. This is clear since $L(\# X) = \# (LX)$. Conversely we have to show that $(\int (\# Z), \int (Z)) \in N_{RV}$. Since $\int$ commutes with RV-sums, we may assume $g$ is constant, with value $a$. But then $L(\# X) = a (LX)$ implies $\int (\# Z) = a \int Z$ as required. This gives (12); (13) is a special case.

9. The Grothendieck semirings of $\Gamma$

Let $T = \text{DOAG}_A$ be the theory of divisible ordered Abelian groups $\Gamma$, with distinguished constants for elements of a subgroup $A$. Let $\text{DOAG}_A[*]$ be the category of all $\text{DOAG}_A$ definable sets and bijections. Our primary concern is not with $\text{DOAG}_A$, but rather a proper subcategory $\Gamma[*]$, having the same objects but only piecewise integral morphisms (Definition 9.1). Our interest in $\Gamma[*]$ derives from this: the morphisms of $\Gamma[*]$ are precisely those that lift to morphisms of $RV[*]$, and it is $K_+ [\Gamma[*]]$ that forms a part of $K_+ [RV[*]]$, (cf. §3.3.3. This category depends on $A$, but will nevertheless be denoted $\Gamma[*]$ when $A$ is fixed and understood.

We will first describe $K(\Gamma^{\text{fin}}[*])$, the subring of classes of finite definable sets. Next we will analyze $K(\text{DOAG}_A)$, obtaining two Euler characteristics. This repeats earlier work by Maříková. We retain our proofs as they give a rapid path to the Euler characteristics, but [26] includes a complete analysis of the semiring $K(\text{DOAG}_A)$, that may well be useful in future applications.

At the level of Grothendieck rings, the categories $\Gamma[*]_A$ and $\text{DOAG}_A$ may be rather close; see Lemma 9.8 and Question 9.9. But the semiring homomorphism $K_+ (\Gamma[*]_A) \to K(\text{DOAG}_A)$ is far from being an isomorphism, and it remains important to give a good description of $K_+ (\Gamma[*]_A)$. We believe that further invariants can be found by mapping $K_+ (\Gamma[*])$ into the Grothendieck semirings of other completions of the universal theory of ordered Abelian groups over $A$, as well as $\text{DOAG}$, in the manner of Proposition 9.2; it is possible that all invariants appear in this way.

A description of $K_+ (\Gamma[*]_A)$ would include information about the Grothendieck group of subcategories, such as the category of bounded definable sets. We will only sample one bit of the information available there, in the form of a “volume” map on bounded subsets of $K_+ [\Gamma[*]]$ into the rationals, and a discrete analogue.
Definition 9.1. An object of $\Gamma[n]$ is a finite disjoint union of subsets of $\Gamma^n$ defined by linear equalities and inequalities with $\mathbb{Z}$-coefficients and parameters in $A$. Given $X, Y \in \text{Ob} \Gamma[n]$, $f \in \text{Mor} \Gamma(X, Y)$ if $f$ is a bijection, and there exists a partition $X = \bigcup_{i=1}^{n} X_i$, $M_i \in \text{GL}_n(\mathbb{Z})$, $a_i \in A^n$, such that for $x \in X_i$, 

$$f(x) = M_i x + a_i$$

$\Gamma^*$ is the category of definable subsets of $\Gamma^n$ for any $n$, with the same morphisms. Since there are no morphisms between different dimensions, it is simply the direct sum of the categories $\Gamma[n]$, and the Grothendieck semi-ring $K_+(\Gamma)$ of $\Gamma[\ast]$ is the graded direct sum of the semigroups $K_+(\Gamma[n])$. We will write $K[\Gamma]$ for the corresponding group.

Let $\Gamma^{\text{bdd}}[\ast]$ be the full subcategory of $\Gamma[\ast]$ consisting of bounded sets, i.e., an element of $\text{Ob} \Gamma^{\text{bdd}}[n]$ is a definable subset of $[-\gamma, \gamma]^n$ for some $\gamma \in \Gamma$.

$\Gamma_A$ is a subcategory of $\Gamma_{\mathbb{Q} \otimes A}$ (a category with the same objects, but more morphisms, generated by additional translations) and this in turn is a subcategory of $\text{DOAG}_{\mathbb{Q} \otimes A}$.

There is therefore always a natural morphism from $K_+(\Gamma_A[\ast])$ to the smaller semigroup $K_+\text{(DOAG}_{\mathbb{Q} \otimes A})$. We will exhibit two independent Euler characteristics on $\text{DOAG}_{\mathbb{Q} \otimes A}$ and show that they define an isomorphism $K(\text{DOAG}_{\mathbb{Q} \otimes A}) \rightarrow \mathbb{Z}^2$. Taking the dimension grading into account, this will give rise to two families of Euler characteristics on $K(\Gamma_A)$, with $\mathbb{Z}[\Gamma]$-coefficients.

9.1. Finite sets. Let $\Gamma^{\text{fin}}[n]$ be the full subcategory of $\Gamma_A[n]$ consisting of finite sets. The Grothendieck semi-ring of $\Gamma^{\text{fin}}[\ast]$ embeds into the semi-rings of both $\Gamma_A$ and RES, within $\Gamma_A$ and $\text{RES}$, within the Grothendieck semi-ring of $\text{RES}_A$. We will see that $K_+\text{(RES}_A)$ is freely generated by them over $K_+(\Gamma^{\text{fin}}[\ast])$. We proceed to analyze $K_+(\Gamma^{\text{fin}}[\ast])$ in detail.

Let $\tau = [0,1] \in K_+(\Gamma^{\text{fin}}[1])$ be the class of the singleton $\{0\}$.

The unit element of $K(\Gamma)$ is the class of $\Gamma^0$. Note that the bijection between $\tau$ and $\Gamma^0$ is not a morphism in $\Gamma[\ast]$; in fact $1, \tau, \tau^2, \ldots$ are distinct and $\mathbb{Q}$-linearly independent in $K(\Gamma)$. The motivation for this choice of category becomes clear if one thinks of the lift to $\text{RES}$; the inverse image of $\tau^n$ in $\text{RES}$ (also denoted $\tau^n$) has dimension $n$, and cannot be a union of isomorphic copies of $\tau^m$ for smaller $m$.

Let $K(\Gamma^{\text{fin}})[\tau^{-1}]$ be the localization. This ring is naturally $\mathbb{Z}$-graded ring; let $H^{\text{fin}}$ be the $0$-dimensional component.

Let $\Xi_A$ be the space of subgroups of $(\mathbb{Q} \otimes A)/A$, or equivalently of subgroups of $\mathbb{Q} \otimes A$ containing $A$. View it as a closed subspace of the Tychonoff space $2^{(\mathbb{Q} \otimes A)/A}$, via the characteristic function $1_s$ of a subgroup $s \in \Xi_A$. Let $C(\Xi_A, \mathbb{Z})$ be the ring of continuous functions $\Xi_A \rightarrow \mathbb{Z}$ (where $\mathbb{Z}$ is discrete).

A cancellation semigroup is a semigroup where $a + b = a + c$ implies $b = c$; in other words, a subsemigroup of an Abelian group.

Proposition 9.2. $K_+(\Gamma^{\text{fin}}[n])$ is a cancellation semigroup. As a semiring, $K_+(\Gamma^{\text{fin}}[\ast])$ is generated by $K_+(\Gamma^{\text{fin}}[1])$. We have:

$$K(\Gamma^{\text{fin}})[\tau^{-1}] = H^{\text{fin}}[\tau, \tau^{-1}]$$

$$H^{\text{fin}} \simeq C(\Xi_A, \mathbb{Z})$$

Proof. Since $\Gamma$ is ordered, any finite definable subset of $\Gamma^n$ is a union of definable singletons. Thus the semi-group $K_+(\Gamma^{\text{fin}}[n])$ is freely generated by the isomorphism classes of singletons $a \in \Gamma^n$, and in particular is a cancellation semigroup. The displayed equality is thus clear; we proceed to prove the isomorphism.

A definable singleton of $\Gamma^n$ has the form $(a_1, \ldots, a_n)$, where for some $N \in \mathbb{N}$, $Na_1, \ldots, Na_n \in A$. So $[(a_1, \ldots, a_n)] = [(a_1) \cdot \ldots \cdot (a_n)]$. 
For any commutative ring \( R \), let \( Idem(R) \) be the Boolean algebra of idempotent elements of a commutative ring \( R \) with the operations \( 1, 0, xy, x + y - xy \). Note that the elements \([a_1, \ldots, a_n]\tau^{-n} \in H_{fin}\) belong to \( Idem(H_{fin}) \); in \( K_+(\Gamma^{fin}) \); for any \( a \in \Gamma \) we have the relation: \([a]^{2} = [a] \tau \). Let \( B \) be the Boolean subalgebra of \( Idem(H_{fin}) \) generated by the elements \([a_1, \ldots, a_n]\tau^{-n} \). For a maximal ideal \( M \) of \( B \), let \( I_M \) be the ideal of \( H_{fin} \) generated by \( M \). Note \( H_{fin} = ZB \). Hence we have to show:

1. The Stone space of \( B \) is \( \Xi_A \)
2. For any maximal ideal \( M \) of \( B \), \( H_{fin}/I_M \simeq Z \) naturally.

For any commutative ring \( R \), \( B \) is a finite Boolean algebra. Let \( \text{Idem}(R) \) be the Boolean ideal of \( \text{Idem}(R) \) generated by a single element \( b \); if \( b \neq 1 \), then \( bR \neq R \) since \( b(1-b) = 0 \). Thus if \( M \) is a proper ideal of \( \text{Idem}(R) \), then \( MR \) is a proper ideal of \( R \). Applying this to \( B \), viewed as a Boolean subalgebra of \( \text{Idem}(\mathbb{Q} \otimes H_{fin}) \), we see that \( I_M \cap Z = (0) \) for any maximal ideal \( M \) of \( B \). Thus the composition \( Z \to H_{fin} \to H_{fin}/I_M \) is injective. On the other hand, \( H_{fin} \) is generated over \( Z \) by the elements \([a]/\tau\), and each of them equals 0 or 1 modulo \( I_M \), so the map is surjective too. This proves the second point.

To prove the first, we define a map \( \Phi : \Xi_A \to \text{Stone}(B) \).

Let \( t = T/A, T \leq \mathbb{Q} \otimes A \). If \([a_1, \ldots, a_n]\tau^{-n} \in GL_n(\mathbb{Z}) \times A^n \), then some element of \( GL_n(\mathbb{Z}) \times A^n \) takes \([a_1, \ldots, a_n]\tau^{-n} \) to \([b_1, \ldots, b_n]\tau^{-n} \); in this case, if \( a_i \in T \) for each \( i \) then \( b_i \in T \) for each \( i \); so \( \Pi_{i=1}^n 1_t(a_i + A) = \Pi_{i=1}^n 1_t(b_i + A) \). Thus, given \( t \in \Xi_A \), we can define a homomorphism \( \Phi_t : H_{fin} \to Z \) by:

\[
[(a_1, \ldots, a_n)]_{\tau^{-n}} \mapsto \Pi_{i=1}^n 1_t(a_i + A)
\]

Let \( M(t) = \ker(h_t) \cap B \).

The map \( \Phi : t \mapsto M(t) \) is clearly continuous. If \( t, t' \) are distinct subgroups, let \( a \in t, a \notin t' \) (say); then \([a]/\tau \in M(t), [a]/\tau \notin M(t') \). So \( \Phi \) is injective. If \( P \) is a maximal filter of \( B \), let \( t_P = \{a + A : [a]/\tau \in P \} \).

Claim \( t_P \) is a subgroup.

Proof:
Suppose \( a + A, b + A \in t_P \) and let \( c = a + b \). Then we have the relation

\([a][b] = [a][b][c]\)

in \( K_+(\Gamma^{fin}) \), arising from the map

\((x, y, z) \mapsto (x, y, xyz)\)

Thus \( ([a]/\tau)([b]/\tau)(1 - [c]/\tau) = 0 \). As \( ([a]/\tau), ([b]/\tau) \in P \) we have \( (1 - [c]/\tau) \notin P \), so \([c]/\tau \in P \).

Clearly \( P = M(t_P) \). Thus \( \Phi \) is surjective, and so a homeomorphism. \( \square \)

Example We always have a homomorphism \( K(\Gamma^{fin}) \to Z \) (by counting points of a finite set in the divisible hull); when \( \mathbb{Z} \) is divisible, this identifies \( K(\Gamma^{fin}) \) with \( Z[\tau] \). In general, we have the surjective morphism \( K(\Gamma^{fin}) \to K(\mathbb{Q} \otimes A) = Z[\tau] \).

Lemma 9.3. Let \( Y \) be an \( A \)-definable subset of \( \Gamma^n \), of dimension \(< n \). Then \( Y \) is a finite union of \( GL_n(\mathbb{Z}) \)-conjugates of sets \( Y_i \subseteq \{c_i\} \times \Gamma^{n-1}, \) with \( c_i \in \mathbb{Q} \otimes A \).

Proof. \( Y \) can be divided into finitely many \( A \)-definable pieces, each contained in some \( A \)-definable hyperplane of \( \Gamma^n \). So we may assume \( Y \) itself is contained in some such hyperplane, i.e. \( \sum r_i d_i = c \) for some \( c \in \mathbb{Q} \otimes \text{val}_c(A) \). We may assume \( r_i \in Z \) and \((r_1, \ldots, r_n)\) have no common divisor. In this case \( \mathbb{Z}^n/Z(r_1, \ldots, r_n) \) is torsion free, hence free, so \( Z(r_1, \ldots, r_n) \) is a direct summand of \( Z^n \). Thus after effecting a transformation of \( GL_n(\mathbb{Z}) \), we may assume \((r_1, \ldots, r_n) = (1, 0, \ldots, 0) \), i.e. \( Y \) lies in the hyperplane \( y_1 = c \). Let \( Z \) be the projection of \( Y \) to the coordinates \( (2, \ldots, n) \). Then \( Y = \{c\} \times Z \). \( \square \)
9.2. Euler characteristics of DOAG. We describe two independent Euler characteristics on $\mathcal{A}$-definable subsets of $\Gamma$, i.e., additive, multiplicative $\mathbb{Z}[\tau]$-valued functions invariant under all definable bijections. The values are in $\mathbb{Z}[\tau]$ rather than $\mathbb{Z}$ because $\Gamma[*] = \mathbb{S}(\Gamma[*])$ is graded by ambient dimension.

Proposition 9.4 - Lemma 9.6 were obtained earlier in [26], and independently in [20].

In fact these two Euler characteristics come from Euler characteristics of DOAG$_{\mathbb{Q}\otimes\mathcal{A}}$. There, they are the only ones:

**Proposition 9.4.** Let $\mathcal{A}$ be a divisible ordered Abelian group. Then $K(\text{DOAG}_\mathcal{A}) \cong \mathbb{Z}^2$.

**Proof.** We begin by noting that there are at most two possibilities.

In DOAG, all definable singletons are isomorphic. The identity element of the ring $K(\text{DOAG})$ is the class of any singleton. Thus the image of $K(\Gamma^{\text{fin}}[*])$ in $K(\text{DOAG}_\mathcal{A})$ is isomorphic to $\mathbb{Z}$.

**Claim** The image of $K(\Gamma^{\text{bdd}}_\mathcal{A})$ in $K(\text{DOAG}_\mathcal{A})$ equals the image of $K(\Gamma^{\text{fin}}[*])$ there.

Translation by $a$ gives an equality of classes in $K(\Gamma)$, $[(a, \infty)] = [(a, \infty))$ so

$$[(0, a)] + \{[pt]\} = [(0, a) = 0.$$

Thus bounded segments are equivalent to linear combinations of points. This can be seen directly by induction on dimension and on ambient dimension: consider the class of a bounded set $Y \subseteq \Gamma^{n+1}$. $Y$ is a Boolean combination of sets of the form $\{(x, y) : x \in X, f(x) < y < g(x)\}$. This is DOAG$_\mathcal{A}$-isomorphic to $Y' = \{(x, y) : x \in X, 0 < y < h(x)\}$, where $h(x) = g(x) - f(x)$.

Let $Z = \{(x, y) : x \in X, y > 0\}, Z' = \{(x, y) : x \in X, y > h(x)\}$. Then the map $(x, y) \mapsto (x, y + h(x))$ shows that $[Z] = [Z']$. On the other hand $Z'$ is the disjoint union of $Z, Y$ and a smaller-dimensional set $W$. Thus $[Z] = [Z'] + [Y] + [W]$ so $[Y] = -[W]$, and by induction $[Y]$ lies in the image of $K(\Gamma^{\text{fin}}[*])$.

Now consider $t = [(0, \infty)] \in K(\Gamma_\mathcal{A})$. We have a homomorphism $K(\Gamma^{\text{bdd}}_\mathcal{A})[t] \to K(\Gamma)$.

To see that it is surjective, again by induction it suffices to look at sets such as $\{(x, y) : x \in X, f(x) < y\}$ or $\{(x, y) : x \in X, f(x) < y < g(x)\}$. The latter is equivalent to a smaller-dimensional set, by induction, as above. The former is equivalent to $\{(x, y) : x \in X, 0 < y\}$ so that it has the class $[X] \times t$ and is thus in the image of $K(\Gamma^{\text{bdd}}_\mathcal{A})[t]$.

Let $T = \{(x, y) : 0 < y \leq x\}$. The map $(x, y) \mapsto (x, y + x)$ takes $T$ to $\{(x, y) : 0 < x < y \leq 2x\}$, so $2[T] = \{[(x, y) : 0 < y \leq 2x]\}$. The same map shows that $t^2 - 2[T] - 2T$ so $[T] = 0$.

But then $\{[(x, y) : 0 < x \leq y]\} = 0$, and adding we obtain: $0 + 0 = t^2 + \{[(x, x) : 0 < x]\} = t^2 + t$.

Thus $K(\text{DOAG}_\mathcal{A})$ is a homomorphic image of $\mathbb{Z}[t]/(t^2 + t) \cong \mathbb{Z}^2$. To see that the homomorphism is bijective, it remains to exhibit a homomorphism $K(\text{DOAG}_\mathcal{A}) \to \mathbb{Z}$ with $t \mapsto 0$ and another with $t \mapsto -1$. The two lemmas below show this, in a form suitable also for a dimension-graded version.

**Lemma 9.5.** There exists a ring homomorphism $\chi : K(\Gamma) \to \mathbb{Z}[\tau]$, with $\chi((0, \infty)) = \tau$. It is invariant under $GL_n(\mathbb{Q})$ acting on $\Gamma^n$.

**Proof.** Let RCF be the theory of real closed fields. See [36] for the existence and definability of an Euler characteristic map $\chi : K(\text{RCF}) \to \mathbb{Z}$. For any definable $X, P, f : X \to P$ of RCF, there exists $m \in \mathbb{N}$ and a definable partition $P = \bigcup_{i < m} P_i$, such that for any $i$, any $M \models \text{RCF}$ and $b \in P_i(M)$, $\chi(X_b) = i$. Here $X_b = f^{-1}(b)$ and $\chi(X_b) = i$ iff there exists an $M$-definable partition of $X_b$ into definable cells $C_j$, with $\sum_{j} (-1)^{\dim(C_j)} = i$.

The language of $\Gamma$ (the language of ordered Abelian groups) is contained in the language of RCF. So if $X, P, f : X \to P$ are definable in the language of ordered Abelian groups, they are RCF-definable. Therefore, the above result specializes, and we obtain an Euler characteristic
map \( \chi : K(\Gamma_A[n]) \to \mathbb{Z} \), valid for any divisible group \( A \). This \( \chi \) is invariant under all definable bijections (not only the morphisms of \( \Gamma[*] \)), and is additive and multiplicative. We have \( \chi(\{0\}) = 1, \chi_{O}(a,b) = -1 \) for \( a < b \), and \( \chi_{O}(0,\infty) = -1 \) too (though \((0,1)\) and \((0,\infty)\) are not definably isomorphic in the linear structure.) Now let \( \chi_O(X) = \chi(X)r^n \) for \( X \subseteq \Gamma^n \), and extend to \( \Gamma[*] \) by additivity. \( \square \)

Remark The Euler characteristic constructed in this proof appears to depend on an embedding of \( A \) into the additive group of a model of RCF. But by the uniqueness shown above it does not. In fact, as pointed out to us by Van den Dries, Ealy and Maříková, an Euler characteristic with the requisite properties is defined in [36] directly for any \( O \)-minimal structure; moreover the use of RCF in the lemma below can also be replaced by a direct inductive argument, and some simple facts about Fourier-Motzkin elimination.

Another Euler characteristic can be obtained as follows: given a definable set \( Y \subseteq \Gamma^n \), let

\[
\chi'(Y) = \lim_{r \to \infty} \chi(Y \cap C_r)
\]

where \( C_r \) is the bounded closed cube \([-r,r]^n \). By \( O \)-minimality, the value of \( \chi(Y \cap C_r) \) is eventually constant.

Note that \( \chi' \) is not invariant under semi-algebraic bijections, since the bounded and unbounded open intervals are given different measures. Still,

**Lemma 9.6.** \( \chi' \) induces a group homomorphism \( K(\Gamma[n]) \to \mathbb{Z} \); and yields a ring homomorphism \( K(\Gamma[*]) \to \mathbb{Z}[r] \). Moreover \( \chi' \) is invariant under piecewise \( GL_n(\mathbb{Q}) \)-transformations.

**Proof.** \( \chi' \) is clearly additive and multiplicative. Isomorphism invariance can be checked as follows: first,

**Claim** If \( X \neq \emptyset \) is defined by a finite number of weak (\( \leq \)) affine equalities and inequalities, then \( \chi'(X) = 1 \).

**Proof.** It suffices to show that this is true in \((\mathbb{R},+)\); since then it is true in any model of the theory of divisible ordered Abelian groups. Now we may compute the Euler characteristic \( \chi \) of the bounded sets \( X \cap C_r \) in \((\mathbb{R}^+,+)\). Let \( p \in X \). For large enough \( r, p \in X \cap C_r \) there is a definable retraction of the closed bounded set \( X \cap C_r \) to \( p \) (along lines through \( p \)). Thus \( X \cap C_r \) has the same homology groups as a point, and so Euler characteristic 1. \( \square \)

To prove the lemma we must show that if \( \phi : X \to Y \) is a definable bijection, \( X, Y \subseteq \Gamma^n \), then \( \chi'(X) = \chi'(Y) \). We use induction on \( \dim(X) \). By additivity, if \( X \) is a Boolean combination of finitely many pieces, it suffices to prove the lemma for each piece. We may therefore assume that \( \phi \) is linear (rather than only piecewise linear) on \( X \). Let \( \phi' \) be a linear automorphism extending \( \phi \). Expressing \( X \) as a union of basic pieces, we may assume \( X \) is defined by some inequalities \( \sum \alpha_i x_i \leq c \), as well as some equalities and strict inequalities. So \( X \) is convex. We have to show that \( \chi'(X) = \chi'((\phi') X) \). Let \( \tilde{X} \) be the closure of \( X \) (defined by the corresponding weak inequalities.) Then \( \tilde{X} \setminus X \) has dimension \( \leq \dim(X) \), so by induction \( \chi'(\phi'(\tilde{X} \setminus X) = \chi'((\phi') \tilde{X} \setminus X) \). But \( \tilde{X} \) is closed and convex, so \( \chi_{O'}(\tilde{X}) = 1 = \chi_{O'}((\phi') \tilde{X}) \). Subtracting, \( \chi'(\phi'(\tilde{X})) = \chi'(\tilde{X}) \).

Once again, using the ambient dimension grading, we can define \( \chi'_O : \Gamma[*] \to \mathbb{Z}[r] \) with \( \chi'_O(x) = \chi'(x)r^n \) for \( x \in \Gamma[n] \).

In the following lemma, all classes are taken in \( K(\Gamma_A)[*] \). Let \( e_a \) be the class in \( K(\Gamma_A)[1] \) of the singleton \{ \( a \) \}, and \( \tau_a \) the class of the segment \((0,a)\).

**Lemma 9.7.** Let \( a \in \mathbb{Q} \otimes A, b \in A \).

1. \( \tau_a = \tau_{a+b} e_a = e_{a+b} \).
2. If \( b \leq c \in A \) then \([b,c] = -e_0 \).
(3) \( e_0^2 = e_a \)
(4) \( \tau_a(e_0) = 0 \)
(5) If \( 2a \in A \) then \( 2\tau_a + e_a = -e_0 \), and \( e_0(e_a - e_0) = 0 \)

Proof. (1) \( \tau_a = [(0,a)] = [(0,\infty)] - [(a, \infty)] - e_a \) and similarly \( \tau_{a+b} \). The map \( x \mapsto x + b \) shows that \( [(a, \infty)] = [(a+b, \infty)] \) and \( e_a = e_{a+b} \), hence also \( \tau_a = \tau_{a+b} \).
(2) \( [(b,c)] = [(b,\infty)] - [(c, \infty)] - e_c = -e_0 \) by (1), since \( c - b \in A \).
(3) The map \( (x, y) \mapsto (x, y + x) \) is an \( SL_2(\mathbb{Z}) \)-bijection between \( \{(a,0)\} \) and \( (a,a) \).
(4) Let

\[ D = \{(x, y) : 0 < x < a, 0 < y \leq x\} \]
\[ D' = \{(x, y) : 0 < y < a, 0 < x \leq y\} \]
\[ D_1 = \{(x, y) : 0 < x < a, y > 0\} \]
\[ T(x, y) = (x, y + x) \]

Then \( T(D_1) = D_1 \setminus D \). Since \( [T(D_1)] = [D_1], [D] = 0 \). Similarly \( [D'] = 0 \). Note also

\[ T((0,a) \times \{0\}) = \{(x, x) : 0 < x < a\} \]

Thus

\[ 0 = [D] + [D'] = [(0,a)^2] + \{(x, x) : 0 < x < a\} = \tau_a^2 + \tau_a e_0 \]

(5) Let \( 0 < 2a \in A \). Then \( [(0,a)] = [(a,2a)] \) using the map \( x \mapsto 2a - x \). So \( 2\tau_a + e_a = [(0,a) \cup \{a\} \cup (a,2a)] = [(0,2a)] = -e_0 \) by (2). So \( (-e_0 - e_0)(e_0 - e_a) = (2\tau_a)(2\tau_a + 2e_0) = 0 \)

by (1). Thus \( e_0^2 = e_a^2 = e_a^2 \).

The next lemma will not be used, except as a partial indication towards the question that follows, regarding the difference at the level of Grothendieck groups between \( GL_n(\mathbb{Z}) \) and \( GL_n(\mathbb{Q}) \) transformations. Let \( Ann(e_0) \) be the annihilator ideal of \( e_0 \); it is a graded ideal. Let \( R = K(\Gamma_A)[*]/Ann(e_0) \), the image of \( K(\Gamma_A)[*] \) in the localization \( K(\Gamma_A)[*][e_0^{-1}] \). In the next lemma, the classes of definable sets are taken in \( R \), viewed as a subring of \( K(\Gamma_A)[*][e_0^{-1}] \). Let \( e_a = e_a/e_0, \tau_a = \tau_a/e_0 \).

Lemma 9.8. Let \( A' = \{a \in \mathbb{Q} \times A : e_a = 1\} \).
(1) If \( X \subseteq \Gamma^n \) is definable by linear inequalities over \( A \), and \( T \in GL_n(\mathbb{Z}) \times (A')^n \), then \( [TX] = [X] \in R \).
(2) \( A' \) is a subgroup of \( \mathbb{Q} \times A \).
(3) \( e_a^2 = e_a, \tau_a(t_a + 1) = 0 \)
(4) \( A' \) is 2-divisible.

Proof. (1) It suffices to show this when \( T \) is a translation by an element \( a \in (A')^n \). The map \( (x, y) \mapsto (x + y, y) \) is in \( SL_n(\mathbb{Z}) \), hence \( [X \times \{a\}] = [TX \times \{a\}] \) in \( K(\Gamma_A)[2a] \). Since \( a \in (A')^n \), \( [a] = e_0^a \). So \( [X]e_0^a = [TX]e_0^a \), and upon dividing by \( e_0^a \) the statement follows.
(2) Clear from (1). For the following clauses, note that by (1),(2), Lemma 9.7 applies with \( A \) replaced by \( A' \).
(3) By Lemma 9.7 (3),(4) divided by \( e_0^2 \).
(4) By Lemma 9.7 (5) applied to \( A' \), if \( 2a \in A' \) then \( e_0(e_a - e_0) = 0 \); so \( e_a - 1 = 0 \), i.e. \( a \in A' \).

Question 9.9. Is it true that \( K(\Gamma_A)[*]/Ann(e_0) = K(\text{DOAG}_A[*])/Ann(e_0) \)?

A positive answer would follow from an extension of (4) to odd primes, over arbitrary \( A \); by an inductive argument, or by integration by parts.
9.3. Bounded sets: volume homomorphism. Let $\tilde{A} = \mathbb{Q} \otimes A$. Recall $\Gamma^{\text{bdd}}[n]$ is the category of bounded $A$-definable subsets of $\Gamma^n$, with piecewise $GL_n(\mathbb{Z}) \ltimes A$ - bijections for morphisms. Let $\text{Sym}(\tilde{A})$ be the symmetric algebra on $\tilde{A}$.

**Proposition 9.10.** There exists a natural “volume” ring homomorphism $K(\Gamma^{\text{bdd}}[*]) \to \text{Sym}(\tilde{A})$

**Proof.** We first work with DOAG without parameters, defining a polynomial associated with a family of definable sets.

Let $C(x,u) = C(x_1, \ldots, x_n; u_1, \ldots, u_m)$ be a formula of DOAG. Write $C_b = \{x : C(x,b)\}$; this is a definable family of definable sets. Assume the sets $C_b$ are uniformly bounded: equivalently, as one easily sees, for some $q \in \mathbb{N}$, for each $i$, $C(x,u)$ implies $|x_i| \leq q \sum_j |u_j|$. For $b \in \mathbb{R}^n$, let $v(b) = \text{vol}(C_b(\mathbb{R}^n))$. Here vol is the Lebesgue measure.

By a constructible function into $\mathbb{Q}$, we mean a $\mathbb{Q}$-linear combination of characteristic functions of definable sets of DOAG. Let $R$ be the $\mathbb{Q}$-algebra of constructible functions into $\mathbb{Q}$.

**Claim 1** There exists a polynomial $P_C(u) \in R[u]$ such that for all $b \in \mathbb{R}^n$, $\text{vol}(C_b(\mathbb{R}^n)) = P_C(b)$.

In other words, the volume of a rational polytope is piecewise polynomial in the parameters, with linear pieces. The proof of the claim is standard, using iterated integration. For each $C$, fix such a polynomial $P_C$.

At this point we re-introduce $A$. Any $A$-definable bounded subset of $\Gamma^n$ has the form $C_b$ for some $C$ as above and some $b \in \tilde{A}^n$.

**Claim 2** If $C_b = C'_b$ then $P_C(b) = P_{C'}(b)$.

**Proof.** (See also below for a more algebraic proof). Fix the formulas $C, C'$. Write $b = Ne, b' = N'e$ where $e \in \tilde{A}^l$ is a vector of $\mathbb{Q}$-linearly independent elements of $\tilde{A}$, and $N, N'$ are rational matrices. Write $P_C = \sum a_\nu(u)u^\nu$ where $a_\nu$ is a constructible function into $\mathbb{Q}$; similarly $P_{C'}$.

Note now that any formula $\psi(x_1, \ldots, x_l)$ of DOAG of dimension $l$ has a solution in $\mathbb{R}^l$ whose entries are algebraically independent. Use this to find algebraically independent $\tilde{e} \in \mathbb{R}^l$ such that $C_{Ne} = C'_{N'e}$, and $a_\nu(N\tilde{e}) = a_\nu(b), a_\nu(N'e) = a_\nu(b')$ for each multi-index $\nu$ of degree $d$.

By definition of $P_C$ we have $P_C(N\tilde{e}) = P_{C'}(N'e)$, so $\sum a_\nu(b)(N\tilde{e})^\nu = \sum a_\nu(b')(N'e)^\nu$. By algebraic independence, $\sum a_\nu(b)(N\tilde{e})^\nu = \sum a_\nu(b')(N'e)^\nu$ as $\mathbb{Q}$-polynomials. So $P_C(Ne) = P_{C'}(N'e)$.

Thus we can define: $v(C_b) = P_C(b)$. Let us show that $v$ defines a ring homomorphism.

Given $C, C'$ one can find $C''$ such that $C''_{b''} = C_b \cup C_{b'}$, and similarly $C''_{b''}$ with $C_{b''} = C_b \cap C_{b'}$. Then $P_C + P_{C'} = P_{C''} + P_{C''''}$. It follows that $v$ is additive. Similarly $v$ is multiplicative, and translation invariant. Since $|\text{det}(M)| = 1$ for $M \in GL_n(\mathbb{Z})$, if $\phi^M(x,u) = \phi(Mx, u)$ then $P^{\phi^M} = P_\phi$.

Van den Dries, Ealy, and Maříková pointed out that Claim 2 can also be reduced to the following statement: if $Q \in R[u]$, $B$ is any $0$-definable set of $\Lambda$, and $Q$ vanishes on $B(\mathbb{R})$, then $Q$ vanishes on $B(\Gamma)$. They prove it as follows: let $\tilde{B}$ be the Zariski closure of $B$; $\tilde{B}$ is clearly a finite union of linear subspaces, and by intersecting $B$ with each of these, we may assume $\tilde{B}$ is linear, so it is cut out by homogeneous linear polynomials $Q_1, \ldots, Q_m$. Each $Q_i$ vanishes on $B(\mathbb{R})$ and hence on $B(\Gamma)$. So $Q$ lies in the (radical) ideal generated by $Q_1, \ldots, Q_m$, hence vanishes on $B(\Gamma)$.
9.3.1. The counting homomorphism in the discrete case. Suppose \( A \) has a least positive element \( 1 \), and assume given a homomorphism \( h_p : A \to \mathbb{Z}_p \) for each \( p \). Then \( A \) embeds into a \( \mathbb{Z} \)-group \( A' \), i.e. an ordered Abelian group whose theory is the theory \( Th(\mathbb{Z}) \) of \( (\mathbb{Z}, <, +) \). (We have \( A \cap (\mathbb{Q} \otimes \mathbb{A}) = \{ a/n \in \mathbb{Q} \otimes \mathbb{A} : (\forall p)(n|h_p(a)) \} \). We have a homomorphism \([X] \mapsto [X(\mathbb{A})]\) from \( K_+(\Gamma[n]) \) to \( K_+(Th(\mathbb{Z})_A) \). On the other hand the polynomial formula for the number of integral points in a polytope defined by linear equations over \( \mathbb{Z} \) yields a homomorphism \( K(Th(\mathbb{Z})^{\text{bdd}}[s]) \to \mathbb{Q}[A] \). By composing we obtain a homomorphism \( K(\Gamma^{\text{bdd}}[s]) \to \mathbb{Q}[A] \).

Remark Using integration by parts one can see that the homomorphism \( K(Th(\mathbb{Z})^{\text{bdd}}[s]) \to \mathbb{Q}[A] \) above is actually an isomorphism.

9.4. The measured case. We repeat the definition of \( \mu \Gamma \) from the introduction, along with two related categories. The category \( \text{vol} \Gamma \) corresponds to integrable volume forms, i.e. those that can be transformed by a definable change of variable to the standard form on a definable subsets of affine \( n \)-space. By Lemma 3.26, the liftable condition in (2) is equivalent to being piecewise in \( GL_n(\mathbb{Z}) \ltimes \mathbb{A}^n \), \( \mathbb{A}^n \) being the group of definable points.

Definition 9.11. (1) For \( c = (c_1, \ldots, c_n) \in \Gamma^n \), let \( \sum(c) = \sum_{i=1}^n c_i \).

(2) For \( n \geq 0 \) let \( \mu \Gamma[n] \) be the category whose objects are pairs \((X, \omega)\), with \( X \in \text{Ob} \Gamma[n] \) and \( \omega : X \to \Gamma \) a definable map. A morphism \((X, \omega) \to (X', \omega')\) is a definable bijection \( f : X \to X' \) liftable to a definable bijection \( \text{val}_v^{-1}X \to \text{val}_v^{-1}X'\), such that \( \sum(x) + \omega(x) = \sum(x') + \omega(x') \) for \( x \in X, x' = f(x) \).

(4) Let \( \mu \Gamma^{\text{bdd}}[n] \) be the full subcategory of \( \mu \Gamma[n] \) with objects \( X \subseteq [\gamma, \infty)^n \) for some \( \gamma \in \Gamma \).

(5) \( \mu \Gamma[n] \) is the direct sum of the \( \mu \Gamma[n] \), and similarly for the related categories.

Recall the Grothendieck rings of functions from §2.2. \( F_n(\Gamma, K_+(\Gamma)) \) is a semigroup with pointwise addition. We also have a convolution product: if \( f \) is represented by a definable \( F \subseteq \Gamma \times \Gamma^{m} \), in the sense that \( f(\gamma) = [F(\gamma)] \), and \( g \) by a definable \( G \subseteq \Gamma \times \Gamma^{n} \), let

\[
 f * g(\gamma) = \{ (a,b,c) : a, b \in F(\alpha), c \in G(\gamma - \alpha) \}
\]

The coordinate \( \alpha \) in the definition is needed in order to make the union disjoint. In general, it yields an element represented by a subset of \( \Gamma \times \Gamma^{m+n+1} \) rather than \( m+n \). But let \( F_n(\Gamma, K_+(\Gamma))[m] \) be the set of \([F] \in F_n(\Gamma, K_+(\Gamma)[n])\) such that \( \dim(F(\alpha)) < n \) for all but finitely many \( \alpha \in \Gamma \). If \( f \in F_n(\Gamma, K_+(\Gamma))[m] \) and \( g \in F_n(\Gamma, K_+(\Gamma))[n] \) then \( f * g \in F_n(\Gamma, K_+(\Gamma))[m+n] \). Let \( F_n(\Gamma, K_+(\Gamma))[n] \) be \( \oplus_{m} F_n(\Gamma, K_+(\Gamma))[m] \), a graded semiring.

Lemma 9.12. (1) \( K_0(\mu \Gamma)[n] \simeq F_n(\Gamma, K_+(\Gamma))[n] \)

(2) \( K_0(\mu \Gamma^{\text{bdd}})[n] \simeq \{ f \in F_n(\Gamma, K_+(\Gamma^{\text{bdd}}))[n] : (\exists \gamma_0)(\forall \gamma_0)(f(\gamma) = 0) \}

(3) \( K_0(\mu \Gamma)[n] \simeq F_n(\Gamma, K_+(\Gamma)[n-1]) \)

Proof. (1) Let \((X, \omega) \in \text{Ob} \mu \Gamma[n] \), with \( X \subseteq \Gamma^n \) and \( \omega : X \to \Gamma \). Let \( d(x) = \omega(x) + \sum(x) \). For \( \alpha \in \Gamma \), let \( X_\alpha = \{ x \in X : d(x) = \alpha \} \). This determines an element \( F(X, \omega) \in F_n(\Gamma, K_+(\Gamma[n])) \), namely \( \alpha \mapsto [X_\alpha] \). It is clear from additivity of dimension that \( \dim(X_\alpha) < n \) for all but finitely many \( \alpha \); so \( F(X, \omega) \in F_n(\Gamma, K_+(\Gamma)[n]) \). If \( h \in \text{Mor}_{\mu \Gamma[n]}(X,Y) \), then by definition of \( \mu \Gamma \) we have \( h(X_\alpha) = Y_\alpha \); so \( X_\alpha = Y_\alpha \) in \( K_+(\Gamma)[n] \). Conversely if for all \( \alpha \in \Gamma \) we have \( X_\alpha = Y_\alpha \) in \( K_+(\Gamma)[n] \), then \( \text{val}_v^{-1}(X_\alpha), \text{val}_v^{-1}(Y_\alpha) \) are \( \alpha \)-definably isomorphic. By Lemma 2.3 there exists a definable \( H : \text{val}_v^{-1}(X) \to \text{val}_v^{-1}(Y) \) such that for any \( x \in \text{val}_v^{-1}(X) \), \( H(x) = h_\alpha(x) \) where \( \alpha = \sum \text{val}_v(x) \). Clearly \( H \) descends to \( \tilde{H} : X \to Y \); by construction \( \tilde{H} \) lifts to \( \mathbb{R} \), and preserves \( \sum \omega, \omega \), so \( \tilde{H} \in \text{Mor}_{\mu \Gamma[n]}(X,Y) \). We have thus shown that \( [X] \to [F(X)] \) is injective. It is clearly a semiring homomorphism.
For surjectivity, let \( g \in \text{Fn}(\Gamma, K_+(\Gamma))[n] \) be represented by \( G \subseteq \Gamma \times \Gamma^n \). It suffices to consider either \( g \) with singleton support \( \{ \gamma_0 \} \), or \( g \) such that \( \dim(G(a)) < n \) for all \( a \in \Gamma \). In the first case, \( g = F(X, \omega) \) where \( X = G(\gamma_0) \) and \( \omega(x) = \gamma_0 - \sum(x) \). In the second: after effecting a partition and a permutation of the variables, we may assume \( G(a) \subseteq \Gamma^{n-1} \times \{ \psi(a) \} \) for some definable function \( \psi(a) \). With another partition of \( \Gamma \), we may assume \( g \) is supported on \( S \subseteq \Gamma \), i.e. \( g(x) = 0 \) for \( x \notin S \), and \( \psi \) is either injective or constant on \( S \). In fact we may assume \( \psi \) is injective on \( S \): if \( \psi \) is constant on \( S \), let \( G' = \{(a, (b_1, \ldots, b_{m-1}, b_n + a)) : (a, (b_1, \ldots, b_n)) \in G, a \in S\} \). Then \( G' \) also represents \( g \), and for \( G' \) the function \( \psi \) is injective. Now let \( X = \bigcup_{a \in S} G(a) \), and let \( \omega(x) = -\sum(x) + \psi^{-1}(x_n) \). Then \( F(X, \omega) = g \).

(2) follows from (1) by restricting the isomorphism.

(3) is proved in a similar manner to (1) though more simply and we omit the details. The key point is that \( GL_n(\mathbb{Z}) \) acts transitively on \( \mathbb{P}^n(\mathbb{Q}) \); this can be seen as a consequence of the fact that finitely generated torsion free Abelian groups are free. More specifically the co-vector \((1, \ldots, 1)\) is \( GL_n(\mathbb{Z}) \)-conjugate to \((1, 0, \ldots, 0)\). Thus the category \( \text{vol}\Gamma[G]\) is equivalent to the one defined using the weighting \( x_1 \) in place of \( \sum(x_i) \). For this category the assertion is clear.

This lemma reduces the study of \( K_+ (\mu \Gamma) \) to that of \( K_+ (\Gamma) \).

10. THE GROTHENDIECK SEMIRINGS OF RV

10.1. Decomposition to \( \Gamma, \text{RES} \). Recall that RV is a structure with an exact sequence

\[
0 \to \mathbb{K}^n \to RV \to \text{val}_\gamma \Gamma \to 0
\]

We study here the Grothendieck semiring of RV in a theory \( T_{RV} \) satisfying the assumptions of Lemma 3.26. The intended case is the structure induced from \( ACV F_A \) for some RV, \( \Gamma \)-generated base structure \( A \).

We show that the Grothendieck ring of RV decomposes into a tensor product of those of RES, and of \( \Gamma \).

The category \( \Gamma[n] \) was described in §9. We used \( GL_n(\mathbb{Z}) \) rather than \( GL_n(\mathbb{Q}) \) morphisms. The reason is given by:

**Lemma 10.1.** The morphisms of \( \Gamma[n] \) are precisely those definable maps that lift to morphisms of \( RV[n] \). The map \( X \to \text{val}_\gamma^{-1}(X) \) therefore induces a functor \( \Gamma[n] \to RV[n] \), yielding an embedding of Grothendieck semirings \( K_+(\Gamma[n]) \to K_+(RV[n]) \).

**Proof.** Any morphism of \( \Gamma[n] \) obviously lifts to RV, since \( GL_n(\mathbb{Z}) \) acts on \( \mathbb{C}^n \) for any group \( C \). The converse is a consequence of Lemma 3.28. □

We also have an inclusion morphism \( K_+(\text{RES}) \to K_+(\Gamma) \).

Observe that \( K_+(\Gamma^{f_m}) \) forms a part of both \( K_+(\text{RES}[\gamma]) \) and \( K_+(\Gamma[n]) \); the embedding of \( K_+(\Gamma[\gamma]) \) into \( K_+(\text{RES}[\gamma]) \) takes \( K_+(\Gamma^{f_m}) \) to a subring of \( K_+(\text{RES}[\gamma]) \), namely the subring generated by the pullbacks of \( \text{val}_\gamma(\gamma), \gamma \in \Gamma \) a definable point.

Given two semirings \( R_1, R_2 \) and a homomorphism \( f_1 : S \to R_1 \), define \( R_1 \otimes_S R_2 \) by the universal property for triples \((R, h_1, h_2)\), where \( R \) a semi-ring and \( h_i : R_i \to R \) a semiring homomorphism, satisfying \( h_1, f_1 = h_2 f_2 \).

We have a natural map \( K_+(\text{RES}) \otimes K_+(\Gamma[\gamma]) \to K_+(\Gamma), [X] \otimes [Y] \mapsto [X \times \text{val}_\gamma^{-1}(Y)] \). By the universal property it induces a map on \( K_+(\text{RES}) \otimes K_+(\Gamma[\gamma]) \). A typical element of the image is represented by a definable set of the form \( \bigcup(X_i \times \text{val}_\gamma^{-1}(Y_i)) \), with \( X_i \subseteq \text{RES}^*, Y_i \subseteq \Gamma^* \).
Proposition 10.2. The natural map $K_+(\text{RES}) \otimes_{K_+(\Gamma_{t=\infty})} K_+(\Gamma[\ast]) \to K_+(\text{RV})$ is an isomorphism.

Proof. Surjectivity is Corollary 3.25. We will prove injectivity. In this proof, $X \otimes Y$ will always denote an element of $K_+(\text{RES}) \otimes_{K_+(\Gamma_{t=\infty})} K_+(\Gamma[\ast])$.

Claim 1 Any element of $K_+(\Gamma[\ast])$ can be expressed as $\sum_{j=1}^m [Y_j] \times \{p_j\}$, for some $Y_j \subseteq \Gamma_i$, $\dim(Y_j) = m_j$, and $p_j \in \Gamma_i$.

Proof. Let $Y \subseteq \Gamma^m$ be definable. If $\dim(Y) < m$, then $Y$ can be partitioned into finitely many sets $Y_j$, each of which lies in some definable affine hypersurface $\sum_{i=1}^m \alpha_i x_i = c_i$ with $\alpha_i \in \mathbb{Q}$, not all 0. In other words $x \mapsto \alpha \cdot x$ is constant on $Y_j$, where $\alpha = (\alpha_1, \ldots, \alpha_m)$. We may assume that each $\alpha_i \in \mathbb{Z}$ and that they are relatively prime. Then $\alpha$ is the first row of a matrix $M \in GL_m(\mathbb{Z})$. The map $x \mapsto Mx$ takes $Y_j$ to a set of the form $Y' \times \{c\}$, $Y' \subseteq \Gamma^{m-1}$. Since $[MY_j] = [Y_j]$ in $K_+(\Gamma[\ast])$, the Claim follows by induction. □

Claim 2 Any element of $K_+(\text{RES}) \otimes_{K_+(\Gamma_{t=\infty})} K_+(\Gamma[\ast])$ can be represented as $\sum_{i=1}^k X_i \otimes \text{val}_v^{-1}Y_i$, where $X_i \subseteq \text{RES}^{m_i}$ and $Y_i \subseteq \Gamma^{m_i}$ are definable sets, and $m_i = \dim Y_i$.

Proof. By definition of $K_+(\text{RES}) \otimes_{K_+(\Gamma_{t=\infty})} K_+(\Gamma[\ast])$ and by Claim 1, any element is a sum of tensors $X \otimes \text{val}_v^{-1}(Y \times \{p\})$; using the $\otimes_{K_+(\Gamma_{t=\infty})}$-relation, $X \otimes \text{val}_v^{-1}(Y \times \{p\}) = (X \times \text{val}_v^{-1}(p)) \otimes Y$. □

Now let $X_i, X'_i \subseteq \text{RES}^*, Y_i, Y'_i \subseteq \Gamma^*$ be definable sets, and let $F : \cup (X_i \times \text{val}_v^{-1}(Y_i)) \to \cup (X'_i \times \text{val}_v^{-1}(Y'_i))$ be a definable isomorphism. Let $m$ be the maximal dimension $m$ of any $Y_i$ or $Y'_i$. Assume (by Claim (2)):

(*) for each $i', Y'_i \subseteq \Gamma^{\dim(Y'_i)}$ and similarly for the $Y_i$.

Claim 3

Let $P$ be a complete type of $Y_i$ of dimension $m$, and $Q$ a complete type of $X_i$. Then $F(Q \times \text{val}_v^{-1}(P)) = Q' \times \text{val}_v^{-1}(P')$ where $Q'$ is a complete type of some $X'_i$, and $P'$ a complete type type of $Y'_i$.

Moreover there exist definable sets $\tilde{P}, \tilde{Q}, \tilde{P}', \tilde{Q}'$ containing $P, Q, P', Q'$ respectively, such that

(1) $F$ restricts to a bijection $\tilde{Q} \times \text{val}_v^{-1}(\tilde{P}) \to \tilde{Q}' \times \text{val}_v^{-1}(\tilde{P}')$.
(2) there exist definable bijections $f : \tilde{P} \to \tilde{P}'$ and $g : \tilde{Q} \to \tilde{Q}'$.
(3) For any $x \in \tilde{Q}, y \in \tilde{P}$, $F$ restricts to a bijection $\{x\} \times \text{val}_v^{-1}(y) \to \{f(x)\} \times \text{val}_v^{-1}(g(y))$.

Proof. By Lemma 3.17, $\text{val}_v^{-1}(P)$ is a complete type; by the same lemma, $Q \times \text{val}_v^{-1}(P)$ is complete; hence so is $F(Q \times \text{val}_v^{-1}(P))$. We have $F(Q \times \text{val}_v^{-1}(P)) \subseteq (X'_i \times \text{val}_v^{-1}(Y'_i))$ for some $i'$. Let $Q' = \text{pr}_1(F(Q \times \text{val}_v^{-1}(P))), V' = \text{pr}_2(F(Q \times \text{val}_v^{-1}(P)))$, $P' = \text{val}_v^{-1}(V') \subseteq Y'_i$, where $\text{pr}_1 : X'_i \times \text{val}_v^{-1}(Y'_i) \to X_i \subseteq \text{RES}, \text{pr}_2 : X'_i \times \text{val}_v^{-1}(Y'_i) \to \text{val}_v^{-1}(Y'_i)$ are the projections. Then $Q', V', P'$ are complete types. We have $m = \dim(P') \geq \dim(Y'_i)$ so by maximality of $m$, equality holds. We thus have $P' \subseteq \Gamma^{\dim(P')}$. By Lemma 3.17, $Q \times \text{val}_v^{-1}(P')$ is also complete type. So $F(Q \times P) = Q' \times \text{val}_v^{-1}(P')$.

By one more use of Lemma 3.17, the function $f_y : x \mapsto \text{pr}_1(F(x,y))$, whose graph is a subset of the stable set $Q \times Q'$, cannot depend on $y \in P$. Thus $f_y = f$, i.e. $F(x,y) = (f(x), \text{pr}_2(F(x,y)))$.

Since $Q \times \text{val}_v^{-1}(y)$ is stable, $\text{val}_v\text{pr}_2 F$ must be constant on it; so $\text{val}_v\text{pr}_2 F(x,y) = g(y)$ on $P \times Q$. This shows that (3) of the “moreover” holds on $P \times Q$. By compactness, it holds on some
definable \( Q \times P \) (and we may take \( f \) injective on \( Q \), and \( g \) on \( P \)). Let \( \tilde{Q} = f(Q), \tilde{P} = g(P) \). Then (1,2) hold also.

Claim 4 Assume (*) holds. Then there exist finitely many definable \( Y^j_i \) \( (j = 0, \ldots, N) \) and \( X^j_i \) such that \( \dim(Y^0_i) < m \), and the conclusion of Claim 3 holds on each \( X^j_i \times \text{val}_v^{-1} Y^j_i \) for \( j \geq 1 \). Moreover we may take the \( Y^j_i \) pairwise disjoint.

Proof. This follows from Claim 3 by compactness; the disjointness can be achieved by noting that if Claim 3 (3) holds for \( \tilde{P}, \tilde{Q} \) then it holds for their definable subsets too.

We now show that if \( \bigcup (X_i \times \text{val}_v^{-1}(Y_i)) \) and \( \bigcup (X'_i \times \text{val}_v^{-1}(Y'_i)) \) are definably isomorphic then \( \sum \beta_i [X_i] \otimes [Y_i] = \sum \beta_i [X'_i] \otimes [Y'_i] \). We use induction on the maximal dimension \( m \) of any \( Y_i \) or \( Y'_i \), and also on the number of indices \( i \) such that \( \dim(Y_i) = m \). Say \( \dim(Y_i) = m \).

By Claim 2, without changing \( \sum \beta_i X'_i \otimes \text{val}_v^{-1}(Y'_i) \) as an element of \( K_+(\text{RES}) \otimes_{K_+(\Gamma^{fin})} K_+(\Gamma[*]) \), we can arrange that \( \dim(Y'_i) = m \), i.e., (*) holds. So Claims 3,4 apply.

The \( Y^j_i \) for \( j \geq 1 \) may be removed from \( Y_1 \), if their images are correspondingly excised from the appropriate \( Y'_j \), since \( [\tilde{Q}] \otimes_{K_+(\Gamma^{fin})} [\tilde{P}] = [f(\tilde{Q})] \otimes_{K_+(\Gamma^{fin})} [g(\tilde{P})] \). What is left in \( Y_1 \) has \( \Gamma \)-dimension \( < m \), and so by induction the classes are equal.

The injectivity and the Proposition follow.

For applications to VF, we need a version of Proposition 10.2 keeping track of dimensions. Below, the tensor product is in the category of graded semirings.

**Corollary 10.3.** The natural map \( K_+(\text{RES}[*]) \otimes_{K_+(\Gamma^{fin})} K_+(\Gamma[*]) \to K_+(\text{RV}[*]) \) is an isomorphism.

**Proof.** For each \( n \) we have a surjective homomorphism

\[ \bigoplus_{k=1}^n K_+(\text{RES}[k]) \otimes K_+(\Gamma[n-k]) \to K_+(\text{RV}[n]) \]

\( K_+ \text{RV}[n] \) can be identified with a subset of the semiring \( K_+ \text{RV} \), namely \( \{ [X] : \dim(X) \leq n \} \).

The proof of Proposition 10.2 shows that the kernel is generated by relations of the form

\[ (X \otimes \text{val}_v^{-1}(Y)) \otimes Z = X \otimes (Y \otimes Z) \]

when \( Y \in K_+(\Gamma^{fin}) \) and \( \dim(X) + \dim(\text{val}_v^{-1}(Y)) + \dim(\text{val}_v^{-1}(Z)) = n \). These relations are taken into account in the ring \( K_+(\text{RES}[*]) \otimes_{K_+(\Gamma^{fin})} K_+(\Gamma[*]) \), so that the natural map \( K_+(\text{RES}[*]) \otimes_{K_+(\Gamma^{fin})} K_+(\Gamma[*]) \to K_+(\text{RV}[*]) \) is injective, hence an isomorphism.

Recall the classes \( e_a = \{ [a] \} \) in \( K(\Gamma[1]) \), defined for \( a \in \Gamma(< \emptyset>) \). They are in \( K_+(\Gamma^{fin}) \), hence identified with classes in \( K(\text{RES}[1]) \), namely \( e_a = \text{val}_v^{-1}(a) \). When denoting classes of varieties \( V \) over the residue field, we will write \( [V] \) for \( [V(k)] \), when no confusion can arise.

**Definition 10.4.** Let \( I \) be the ideal of \( K(\text{RES}[*]) \) generated by all differences \( e_a - e_0 \), where \( a \in \Gamma(< \emptyset>) \). Let \( !K(\text{RES}[*]) = K(\text{RES}[*]) / I \).

By Lemma 9.7 (3), the natural homomorphism \( K(\text{RES}[*]) \) into the localization of \( K(\text{RV}[*]) \) by all classes \( e_a \) factors through \( !K(\text{RES}[*]) \).

Since \( I \) is a homogeneous ideal, \( !K(\text{RES}[*]) \) is a graded ring.

The theorem that follows, when combined with the canonical isomorphisms \( K(\text{VF}[n]) \to K(\text{RV} \leq n)/I_{sp} \) and \( K(\text{VF}) \to K(\text{RV}[*])/I_{sp} \), yields homomorphisms

\[ K : K(\text{VF}) \to !K(\text{RES})[[\hat{A}_1(k)^{-1}]] \]
\[ f' : K(VF) \to !K(RES) \]

**Theorem 10.5.**

1. There exists a group homomorphism
   \[ \varepsilon_n : K(RV[\leq n])/I_{sp} \to !K(RES[n]) \]
   with:
   \[ [RV^{>0}]_1 \mapsto -[\mathbb{A}^{n-1} \times G_m]_n \]
   and
   \[ [X]_k \mapsto [X \times \mathbb{A}^{n-k}]_n \]
   for \( X \in RES[k] \)
2. There exists a ring homomorphism \( \varepsilon : K(RV[\ast])/I_{sp} \to !K(RES)[[A_1]]^{-1} \) with \( \varepsilon([X]_k) = [X]_k / \mathcal{A}_k \) for \( X \in RES[k] \).
3. There exists a group homomorphism
   \[ \varepsilon'_n : K(RV[\leq n])/I_{sp} \to !K(RES[n]) \]
   with \( [RV^{>0}]_1 \to 0 \), and \([X]_k \mapsto [X]_n \) for \( X \in RES[k] \).
4. There exists a ring homomorphism \( \varepsilon' : K(RV[\ast])/I_{sp} \to !K(RES) \) with \( \varepsilon'([X]_k) = [X]_k \) for \( X \in RES[k] \).

**Proof.**

1. We first define a homomorphism \( \chi[m] : K(RV[m]) \to !K(RES[m]) \). By Corollary 10.3,
   \[ K(RV[m]) = \bigoplus_{l=1}^m K(RES[m-l]) \otimes_{K_+((\mathbb{A}_1)^{\infty})} K(\Gamma[l]) \]
   Let \( \chi_0 = Id_{KRES[m]} \). For \( l \geq 1 \) recall the homomorphism \( \chi : K(\Gamma[l]) \to \mathbb{Z} \) of Lemma 9.5. It induces \( \chi_l : K(RES[k]) \otimes_{K_+((\mathbb{A}_1)^{\infty})} K(\Gamma[l]) \to !K(RES[k]) \) by \( a \otimes b \mapsto \chi(b) \cdot [G_m]_l \cdot a \).
   Define a group homomorphism
   \[ \chi[m] : K(RV[m]) \to K(RES[m]), \quad \chi[m] = \bigoplus \chi_l \]
   We have
   \[ \chi[m_1 + m_2](ab) = \chi[m_1](a)\chi[m_2](b) \]
   when \( a \in K(RV[m_1]), b \in K(RV[m_2]) \). This can be checked on homogeneous elements with respect to the grading \( \oplus \mathbb{A}_k \).
   We compute: \( \chi[1]([RV^{>0}]_1) = \chi(1 \otimes [G_m]) = -[G_m] \in K(RES[1]). \)
   Next define a group homomorphism \( \beta_m : !K(RES[m]) \to !K(RES[n]) \) by \( \beta_m([X]) = [X \times \mathbb{A}^{n-m}] \).\]
   Define \( \gamma : \oplus_{m \leq n} K(RV[m]) \to !K(RES[n]) \) by \( \gamma = \sum \beta_m \circ \chi[m] \).
   Then \( \gamma \) is a group homomorphism, and \( \gamma(a) \gamma(b) = \gamma(ab) \cdot [\mathbb{A}^{n}] \) for \( a \in K(RV[m_1]), b \in K(RV[m_2]), m_1 + m_2 \leq n \). Again this is easy to verify on homogeneous elements.
   Finally we compute \( \gamma \) on the standard generator \( J = [RV^{>0}]_1 + [1]_0 - [1]_1 \) of \( I_{sp} \). Since \( \chi[1]([RV^{>0}]_1) = -[G_m] \), we have
   \[ \gamma([RV^{>0}]_1) = \beta_1(-[G_m]) = -[G_m \times \mathbb{A}^{n-1}]_1 \]
   On the other hand
   \[ \gamma([1]_0) = \beta_0([1]_0) = [\mathbb{A}^{n}]_n \]
   \[ \gamma([1]_1) = \beta_1([1]_1) = [\mathbb{A}^{n-1}]_n \]
   So \( \gamma(J) = [\mathbb{A}^{-1}][n-1]_n . \) This is thus induced.

2. For \( a \in K(RV[m]) \), let \( \varepsilon(a) = \beta_m(a) / [\mathbb{A}^{n}]_n \). For any large enough \( n \) we have \( \varepsilon(a) = \varepsilon_n(a) / [\mathbb{A}^{n}] \). The formulas in (1) prove that \( \varepsilon \) is a ring homomorphism.
(3.4) The proof is similar, using $\chi'$ from Lemma 9.6 in place of $\chi$ of Lemma 9.5, and the identity in place of $\beta_m$. □

**Corollary 10.6.** The natural morphism $K(RES[n]) \to K(RV[\leq n])/\mathcal{I}_{sp}$ has kernel contained in $\mathcal{I}$. □

**Lemma 10.7.** Let $T = ACVF_{F(t)}$ or $T = ACVF^R_{F(t)}$, $F$ a field of characteristic 0, with $\text{val}(F) = (0)$, $\text{val}(F(t)) = \mathbb{Z}$, and $\text{val}(t) = 1 \in \mathbb{Z}$. Then there exists a retraction $\rho_t : K_+(RES) \to K_+(Var_F)$. It induces a retraction $!K(RES) \to K(Var_F)$.

**Proof.** Let $t_n \in F((t))^{alg}$ be such that $t_1 = t$ and $t_n^m = t$. For $m = m/n \in \mathbb{Q}$, with $m \in \mathbb{Z}$, $n \in \mathbb{N}$, let $t_\alpha = t_n^m$. So $\alpha \to t_\alpha$ is a homomorphism $\mathbb{Q} \to G_m(F((t))^{alg})$.

Let $V(\alpha) = \text{val}_\alpha^{-1}(\alpha)$. Let $t_\alpha = rv(t_\alpha)$. Then $t_\alpha \in V(\alpha)$.

Let $X \in RES[n]$. Then for some $\alpha_1, \ldots, \alpha_n \in \mathbb{Q}$ we have $X \subseteq \Pi_{i=1}^n V(\alpha_i)$, where $V(\alpha_i) = \text{val}_\alpha^{-1}(\alpha_i)$. Define $f(x_1, \ldots, x_n) = (x_1/t_{\alpha_1}, \ldots, x_n/t_{\alpha_n})$. Then $f$ is $F((t^{1/m}))$-definable for some $m$, but not in general definable. Nevertheless, $F(X) = Y$ is definable. This is because the Galois group $G = \text{Aut}(F^a((t^{1/m}))/F^a((t)))$ extends to a group of valued field automorphisms $\text{Aut}(k((t^{1/m}))/k((t)))$ fixing the entire residue field $k$; while $Y \subseteq k$; thus $G$ fixes $Y$ pointwise and hence setwise.

The map $X \to Y$ of definable sets described above clearly respects disjoint unions. It also respects definable bijections: if $h : X \to X'$ is a definable bijection, $Y = f(X), Y' = f(Y')$, then $fh^{-1}$ is an $F((t^{1/m}))$-definable bijection $Y \to Y'$; by the Galois argument above, it is in fact definable.

The definable subsets of $k$ are just the $F$-constructible sets. Thus we have an induced homomorphism $\rho_t : K_+(RES) \to K_+(Var_F)$; it is clearly the identity on $K_+(RES)$. It induces a homomorphism $K(RES) \to K(Var_F)$.

Finally $\rho_t(\text{val}_\alpha^{-1}(\alpha)) = [G_m]$ for any $\alpha \in \mathbb{Q}$; so a homomorphism on $!K(RES)$ is induced. □

This example can be generalized as follows. Let $L$ be a valued field with residue field $F$ of characteristic 0, $T = ACVF_L$ or $ACVF^R_L$. Let $A = \text{res}(L), A = \mathbb{Q} \otimes A$, and let $t : A \to G_m(L^a)$ be a monomorphism, with $t(A) \subseteq G_m(L)$. Then there exists a retraction $\rho_t : K_+(RES) \to K_+(Var_F)$.

From Theorem 10.5 and Lemma 10.7 we obtain the example discussed in the introduction:

**Proposition 10.8.** Let $T = ACVF^R_{F(t)}$, $F$ a field of characteristic 0, with $\text{val}(F) = (0)$ and $\text{val}(t) = 1 \in \mathbb{Z}$. Then there exists a ring homomorphism $\varepsilon'_t : K(VF) \to K(Var_F)[[\mathbb{A}^1_\Gamma]]^{-1}$, with $[N] \mapsto [-G_m]/[G_\alpha], L([X]_k) \to [X]/[\mathbb{A}_k]$ for $X \in Var_F[k]$. There is also a ring homomorphism $\varepsilon''_t : K(VF) \to K(Var_F)$ with $L([X]_k) \mapsto [X]_k$.

### 10.2. Decomposition of $\mu_{RV}$. An analogous decomposition is valid for the measured Grothendieck semiring $\mu_{RV}$ (Definition 8.13).

**Lemma 10.9.** There exists a homomorphism $K_+\mu_{\Gamma}[n] \to K_+\mu_{\Gamma}RV[n]$ with $[(X, \omega)] \mapsto [\text{val}_\omega^{-1}(X), Id_{\omega} \circ \text{val}_\omega]$.

**Proof.** We have to show that an $\mu_{\Gamma}[\mathbb{N}]$-isomorphism $X \to Y$ lifts to an $\mu_{\Gamma}RV[\mathbb{N}]$-isomorphism. This follows immediately from the definitions. □

Recall $\mu_{\Gamma}RES$ from Definition 8.13. Along the lines of Lemma 9.12, we can also describe $K_+\mu_{\Gamma}RES[n]$ as the semigroup of functions with finite support $\Gamma \to K_+(RES[n])$. We also have the inclusion $K_+\mu_{\Gamma}RES[n] \to K_+\mu_{\Gamma}RV[n], [(X, f)] \mapsto [(X, f, 1)]$. 
Let $\mu_{\Gamma^{f\text{fin}}[n]}$ be full subcategory of $\mu_{\Gamma}[n]$ whose objects are finite. We have a homomorphism $K_+(\mu_{\Gamma^{f\text{fin}}}[n]) \rightarrow \mu_{\Gamma}RES[n]$, $(X, \omega) \mapsto (\text{val}_{\nu^{-1}}(X), \text{Id}, \omega \circ \text{val}_{\nu})$. As before we obtain a homomorphism $K_+(\mu_{\Gamma}RES[*]) \otimes_{K_+(\mu_{\Gamma^{f\text{fin}}}[n])} K_+(\mu_{\Gamma}[*]) \rightarrow K_+(\mu_{\Gamma}(RV[*])).$

Let $\text{RES}_{\Gamma^{\text{vol}}}$ be the full subcategory of $\text{RV}_{\Gamma^{\text{vol}}}$ whose objects are in $\text{RES}$; this is the same as $\text{RV}$ except that morphisms must respect $\sum \text{val}_{\nu}$. Let $\text{vol}_{\Gamma^{\text{fin}}}$ be the subcategory of finite objects of $\text{vol}_{\Gamma}$.

**Proposition 10.10.** (1) The natural map $K_+(\mu_{\Gamma}RES[*]) \otimes_{K_+(\mu_{\Gamma^{f\text{fin}}}[n])} K_+(\mu_{\Gamma}[*]) \rightarrow K_+(\mu_{\Gamma}(RV[*]))$ is an isomorphism.

(2) So is $K_+(\text{RES}_{\Gamma^{\text{vol}}}[*]) \otimes_{K_+(\text{vol}_{\Gamma^{\text{fin}}}[n])} K_+(\text{vol}_{\Gamma}[*]) \rightarrow K_+(\text{RV}_{\Gamma^{\text{vol}}}[*])$.

(3) The decompositions of this section preserve the subsemirings of bounded sets.

**Proof.** We first prove surjectivity in (1). By the surjectivity in Corollary 10.3, it suffices to consider a class $c = [(X \times \text{val}_{\nu}^{-1}(Y), f, \omega)]$ with $X \in \text{RES}[k], Y \subseteq \Gamma^\ell, f(x, y) = (f_0(x), y), \omega : X \times \text{val}_{\nu}^{-1}(Y) \rightarrow \Gamma$. In fact as in Proposition 10.2 we may take $\dim(Y) = l$, and inductively we may assume that any class $[(X' \times Y', f', \omega')]$ with $\dim(Y') < l$ is in the image. Since we may remove a subset of $Y$ of smaller dimension, applying Lemma 3.17 to $\omega : X \times \text{val}_{\nu}^{-1}(Y) \rightarrow \Gamma$, we may assume $\omega(x, y) = \omega'(\gamma)$ when $\text{val}_{\nu}(y) = \gamma$. Now $c = [(X, f_0, 1)] \otimes [(Y, \omega')].$

The proof of surjectivity in (2) is similar.

The proof of injectivity in (1,2) is the same as of Proposition 10.2 and Corollary 10.3. (3) is clear by inspection of the homomorphisms.

We now deduce Theorem 1.3. For a finite extension $L$ of $\mathbb{Q}_p$, write $\text{vol}_L(U)$ for $\text{vol}_L(U(L))$. Let $r$ be the ramification degree, i.e. $\text{val}(L^*) = (1/r)\mathbb{Z}$. Let $Q = q^r$. The normalization is such that $M$ has volume 1; so an open ball of valuative radius $\gamma$ has volume $q^{r\gamma} = Q^\gamma$. Thus the volume of $\text{val}_{\nu}^{-1}(\gamma)$ is $(q - 1)Q^\gamma$. Also the norm satisfies $|y| = Q^{\text{vol}(y)}$.

**Proof of Theorem 1.3.** For $a \in \Gamma^k$ let $Z(a) = \{x \in \hat{O}_{\Gamma}^k : \text{val}(f_1(x)) = a_1, \ldots, \text{val}(f_k(x)) = a_k\}$. Then

$$\int_{O_{\Gamma}^k} |f|^s = \sum_{a \in [\Gamma^{\geq 0}]} Q^{s\text{vol}_{L}(Z(a))}$$

According to Proposition 4.5 and Proposition 10.10 we can write

$$Z(a) \sim \bigcup_{i=1}^{k} L\mathfrak{x}_i \times L\Delta_i(a)$$

where $\Delta_i$ is a definable subset of $\Gamma^{n_1(i)}$, $h_i : \Delta_i \rightarrow \Gamma^k$ the projection to the first $k$ coordinates, $\Delta_i(a) = \{d \in \Gamma^{n_1(i)} : h_i(d) = a\}, \mathfrak{x}_i = (X_i, f_i) \in \text{RES}[n_1(i)], \approx \text{ denotes equivalence up to an admissible transformation.}$

Thus

$$\text{vol}_{L}(Z(a)) = \text{vol}_{L}(\bigcup_{i=1}^{k} L\mathfrak{x}_i \times L\Delta_i(a)) = \sum_{i=1}^{k} \text{vol}_{L}(L\mathfrak{x}_i)\text{vol}_{L}(L\Delta_i(a))$$

If $b = (b_1, \ldots, b_{k+n_2(\gamma)}) \in \Delta_i$, let $h_i^{\gamma}(b)$ be the sum of the last $n_2(\gamma)$ coordinates.

Since $\text{val}_{\nu}$ takes only finitely many values on a definable subset of RES, we may assume $\sum \text{val}_{\nu}(f(x)) = \gamma(i)$ is constant on $x \in \mathfrak{x}_i$. Then $\text{vol}_L(L\mathfrak{x}_i(L)) = Q^\gamma |X_i(L)|$. Thus

$$\int_{O_{\Gamma}^k} |f|^s = \sum_{i} |X_i(L)|Q^{\gamma(i)} \sum_{a \in [\Gamma^{\geq 0}]} Q^{s\text{vol}_{L}(L\Delta_i(a))}$$

Now $\text{vol}_{L}(L\Delta_i(a)) = \sum_{b \in \Delta_i, h(b) = a} (q - 1)^{n_2(\gamma)}Q^{h(b)}$. So

$$\int_{O_{\Gamma}^k} |f|^s = \sum_{i} |X_i(L)|Q^{\gamma(i)} \sum_{a \in [\Gamma^{\geq 0}]} Q^{s\text{vol}_{L}(L\Delta_i(a))}$$

Now $\text{vol}_{L}(L\Delta_i(a)) = \sum_{b \in \Delta_i, h(b) = a} (q - 1)^{n_2(\gamma)}Q^{h(b)}$. So
\[ \sum_{a \in (\Gamma \cdot \mathbb{Z})^h} Q^a d\text{vol}_{\mu}(L \Delta_i(a)) = \sum_{b \in \Delta_i} Q^{s_k h_3(b)+\cdots+s_s h_s(b)}(q-1)^{n_2(i)} Q^{h_0(b)} = (q-1)^{n_2(i)} \text{ev}_{h^i,s,Q}(\Delta_i) \]

The theorem follows from Equations (15),(16). \(\square\)

Let \( A \) be the set of definable points of \( \Gamma \). Recall that for \( X \subseteq \text{RV} \), \([X]_1\) denotes the class \([(X, I_d X)] \in \text{RV}[1] \) of \( X \) with the identity map to \( \text{RV} \), and the constant form \( 1 \). For \( a \in A \), let \( \tilde{e}_a = [(\text{val}_{\nu}^{-1}(0), I_d a)] \in \text{RES}[1] \), \( f_a = \{x\} \), \( I_d a \in \text{RES}[1] \) where \( a \) in the third coordinate is the constant function with value \( a \). If \( a \) lifts to a definable point \( d \) of \( \text{RV} \), multiplication by \( d \) shows that \( \tilde{e}_a = [(\text{val}_{\nu}^{-1}(a), I_d 0)] \), \( f_a = \{0\} \), \( I_d 0 \). Note \( \tilde{e}_a \tilde{e}_b = \tilde{e}_{a+b} \tilde{e}_0 \) and \( \tilde{e}_0 = [G_m] \). Let \( \tau_0 \in \text{RES}[1] \) be the class of \((\text{val}_{\nu}^{-1}((a, \infty)), I_d 0) \). The generating relation of \( \mu^t I_p \) is thus \((\tau_0, f_0) \) (Lemma 8.20 (6)). Let \( \mathfrak{h} \) be the class of \([\text{RV}^{>0}, I_d x^{-1}] \).

Let \( \Lambda^\mu_\mu \) be the ideal of \( K(\mu^t \text{RES}[\ast]) \) generated by the relations \( \tilde{e}_{a+b} = [(\text{val}_{\nu}^{-1}(a), I_d b)] \), \( \mathfrak{a}, \mathfrak{b} \in A \), \( b \) denoting the constant function \( b \). Let \( \tilde{\Lambda}^\mu_\mu \) be the ideal generated by \( \Lambda^\mu_\mu \) as well as the element \([\mathfrak{a}_1] \).

**Theorem 10.11.** There exist two graded ring homomorphisms
\[ \int, \int' : K^\text{eff}(\mu^t \text{RF}[\ast]) \to K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu \]
such that the composition \( K(\mu^t \text{RES}[\ast]) \to K(\mu^t \text{RF}[\ast]) / \Lambda^\mu_\mu \to K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu \) equals the natural projection \( \pi : K(\mu^t \text{RES}[\ast]) \to K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu ; \) with
\[ \int \mathfrak{h} = -[0_1], \quad \int' \mathfrak{h} = 0 \]

**Proof.** The identification \( K^\text{eff}(\mu^t \text{RF}[\ast]) = K(\mu^t \text{RF}[\ast]) / \Lambda^\mu_\mu \) is given by Theorem 8.28, and we work with \( K(\mu^t \text{RF}[\ast]) / \Lambda^\mu_\mu \).

According to Proposition 10.10, we can identify
\[ K(\mu^t \text{RF}[\ast]) = K(\mu^t \text{RES}[\ast]) \otimes_{K^t(\mu^t f^{\text{fin}})} K(\mu^t f^{\text{fin}}) \]

We first construct two homomorphisms of graded rings \( R, R' : K(\mu^t \text{RF}[\ast]) \to K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu \). This amounts to finding graded ring homomorphisms \( K(\mu^t f^{\text{fin}}) \to K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu \) agreeing with \( \pi \) on the graded ring \( K_0(\mu^t f^{\text{fin}}) \). It will be simpler to work with \( R, R' \) together, i.e. construct
\[ R'' = (R, R') : K(\mu^t f^{\text{fin}}) \to (K(\mu^t \text{RES}[\ast]) / \Lambda^\mu_\mu)^2 \]

Recall from Lemma 9.12 the isomorphism
\[ \phi : K(\mu^t f^{\text{fin}}) \to F_n(\mu^t f^{\text{fin}}) / K(\Gamma)[n] \]

Let \( \chi'' : K(\Gamma)[n] \to \mathbb{Z}^2 \) be the Euler characteristic of Proposition 9.4; so that \( \chi'' = (\chi, \chi') \), cf. Lemmas 9.5.9.6. We obtain by composition a map \( E''_n = (E_n, E'_n) : F_n(\Gamma, K(\Gamma)[n]) \to F_n(\Gamma, \mathbb{Z})^2 \). Here \( F_n(\Gamma, \mathbb{Z}) \) is the group of functions \( g : \Gamma \to \mathbb{Z} \) such that \( g(\Gamma) \) is finite and \( g^{-1}(\mathbb{Z}) \) is a definable subset of \( \Gamma \) (a finite union of definable intervals and points.) Thus \( F_n(\Gamma, \mathbb{Z}) \) is freely generated as an Abelian group by \( \{p_a, q_a, r\} \) where \( r \) is the constant function \( 1 \), and for \( a \in A \), \( p_a, q_a \) are the characteristic functions of \( \{a\}, \{(a, \infty)\} \), respectively. Define \( \psi_n : F_n(\Gamma, \mathbb{Z}) \to K(\mu^t \text{RES}[\ast]) \):
\[ \psi_n(p_a) = [G_m]^{n-1} \tilde{e}_a = [G_m]^{n} f_a, \quad \psi_n(q_a) = -[G_m]^{n} f_a, \quad \psi_n(r) = 0 \]

For \( u \in K(\mu^t f^{\text{fin}}) \), let \( R''(u) = \psi_n(E''_n(\phi(u))) \).
Claim \( R'' : K(\mu \Gamma[*]) \to K(\mu \Gamma RES[m])^2 \) is a graded ring homomorphism.

Proof. We have already seen that \( \phi \) is a ring homomorphism, so it remains to show this for \( \psi_* \circ E''_n \).

Now by Proposition 9.4, \( \chi''(Y) = \chi''(Y') \) iff \( [Y] = [Y'] \) in the Grothendieck group of DOAG. Hence given a families \( Y_1, Y_\nu \) of pairwise disjoint sets with \( \chi''(Y_1) = \chi''(Y_\nu) \), by Lemma 2.3 we have \( \chi''(\cup Y_1) = \chi''(\cup Y_\nu) \). From this and the definition of multiplication in \( F(\Gamma, K(\Gamma))[\ast] \), and the multiplicativity of \( E''_n \), it follows that if \( E''_n(f) = E''_n(f') \) and \( E''_m(g) = E''_m(g') \) then \( E''_{n+m}(fg) = E''_{n+m}(f'g') \). In other words, \( E''_n \) is a graded homomorphism from \( F(\Gamma, Z)^2, * \) for some uniquely determined multiplication \( * \) on \( F(\Gamma, Z)^2 \). Clearly \( (a, b) * (c, d) = (a_1 c, b_2 d) \) for two operations \( *_1, *_2 \) on \( F(\Gamma, Z) \).

Now we can compute these operations explicitly on the generators:

\[
p_a \ast p_b = p_{a+b}, \quad p_a \ast q_b = q_{a+b}, \quad q_a \ast q_b = -q_{a+b}
\]

for both \( \ast_1 \) and \( \ast_2 \), and

\[
\begin{align*}
    r \ast_1 e_a &= r, \quad r \ast_1 q_a = -r, \quad r \ast r = r \\
    r \ast_{*2} e_a &= -r, \quad r \ast_{*2} q_a = 0, \quad r \ast_{2} r = -r
\end{align*}
\]

composing with \( \psi \), we see that \( R'' \) is indeed a graded ring homomorphism.

Let \( R, R' \) be the components of \( R'' \).

Claim \( R, R', \pi \) agree on \( K_+(\mu \Gamma_{f[m]}) \). \( R(\overline{m}) = R'(\overline{m}) = -\overline{e}_0 \).

This is a direct computation. It follows that \( R, R' \) induce homomorphisms \( K(\mu \Gamma RV[*]) \to K(\mu \Gamma RES[*]) \). Since \( \overline{e}_0 + f_0 = [(\overline{A}_1, Id, 0)], \mod \overline{I}_\mu \) both \( R, R' \) equalize \( \mu \Gamma I_{sp} \), and hence induce homomorphisms on \( K(\mu \Gamma RV[*]) / \mu \Gamma I_{sp} \to K(\mu \Gamma RES[*]) / \overline{I}_\mu \). \( \square \)

Remark

The construction is heavily, perhaps completely constrained. The value of \( \psi_m(p_a) \) is determined by the tensor relation over \( K_+(\mu \Gamma_{f[m]}) \). The value of \( \psi_m(q_a) \) is determined by the relation \( I_{sp} \). The choice \( \psi(r) = 0 \) is not forced, but the multiplicativitiy relation shows that either \( r \) or \( -r \) is idempotent, so one has a product of two rings, with \( \psi(r) = 0 \) and with \( \psi(r) = \pm 1 \). In the latter case we obtain the isomorphisms of Theorem 10.5. Thus the only choice involved is to factor the fibers of an element of \( F(\Gamma, K(\Gamma))[\nu] \) through \( \chi'' \), i.e. through \( K(\Gamma, DOAG) \). It is possible that \( K(\Gamma[n]) = K(\Gamma DOAG[n]) \) (cf. Question 9.9). In this case, \( f, f', f'' \) are injective and determine \( K(\mu \Gamma VF[*]) \) completely, at least when localized by the volume of a unit ball.

11. Integration with an additive character

Let \( \Omega = \text{VF}/M \). Let \( \psi : \text{VF} \to \Omega \) be the canonical map.

Motivation: for any \( p \), \( \Omega(\Omega_p) \) can be identified with the \( p \)-th power roots of unity via an additive character on \( \mathbb{Q}_p \). For other local fields, the universal \( \psi \) we use is tantamount to integration with respect to all additive characters of conductor \( M \) at once. Thus \( \Omega \) is our motivic analog of the roots of unity, and the natural map \( \text{VF} \to \text{VF}/M \) an analogue of a generic additive character.

Throughout this paper we have been able to avoid subtractions and work with semi-groups, but here it appears to be essential to work with a group or at least a cancellation semigroup. The reason is that we will introduce, as the essential feature of integration with an additive character, an identification of the integral of a function \( f \) with \( f + g \) if \( g \) is \( \partial \)-invariant. This corresponds to the rule that the sum over a subgroup of a nontrivial character vanishes. Now for any \( h : \Omega \to K_+(\mu VF) \), it is easy to construct \( h' : \Omega \to K_+(\mu VF) \) such that \( h + h' \) is...
$\mathcal{O}$-invariant. Thus if $f + h = f' + h$ for some $h$, then $f = f + h + h' = f' + h + h' = f'$. So cancellation appears to come of itself. 

If we allow all definable sets and volume forms, a great deal of collapsing is caused by the cancellation rule. We thus use the classical remedy and work with bounded sets and volume forms. The setting is flexible and can be compatible with stricter notions of boundedness. This is only a partial remedy in the case of higher dimensional local fields, cf. Example 12.12.

The theory can be carried out for any of the settings we considered. Let $\mathcal{R}$ be one of these groups or rings, with $\mathcal{D}$ the corresponding data. For instance: $\mathcal{D}$ the set of pairs $(X, \phi)$ with $X$ a bounded definable subset of $\text{VF}^n \times \text{RV}^*$, and $\phi : X \to \text{RV}$ a bounded definable function; $\mathcal{R}$ the corresponding Grothendieck ring. Similarly we can take $\Gamma$-volumes, or pure isomorphism invariants without volume forms. In this last case there is no point restricting to bounded sets. As we saw, two Euler characteristics into the Grothendieck group of varieties over $\text{RES}$ do survive.

In each case, we we think of $\mathcal{R}$ as a Grothendieck ring of associated RV-data, modulo a canonical ideal.

Everything can be graded by dimension, but for the moment we have no need to keep track of it, so in the volume case we can take the direct sum over all $n$ or fix one $n$ and omit it from the notation.

The corresponding group for the theory $T_A$ or $T_{<a}$ will be denoted $\mathcal{R}_A, \mathcal{R}_a$, etc. When $V$ is a definable set, we let $\mathcal{D}_V, \mathcal{R}_V$ denote the corresponding objects over $V$. For instance in the case of bounded RV-volumes, $\mathcal{D}_V$ is the set of pairs $(X \subseteq V \times W, \phi : X \to \text{RV}^*)$ such that for any $a \in V$, $(X_a, \phi|X_a)$ with $X_a$ bounded.

If $\mathcal{R}$ is our definable analog of the real numbers (as recipients of values of $p$-adic integration), the group ring $\mathbb{C} = \mathbb{R}[\mathcal{O}]$ will take the role of the complex numbers. We have a canonical group homomorphism $(\text{VF}, +) \to \mathbb{C} \subseteq \mathbb{C}_a(\mathbb{C})$, corresponding to a generic additive character.

Integration with an additive character can be presented in two ways: in terms of definable functions $f : X \to \Omega$ (Riemann style), where we wish to evaluate expressions such as $\int_X f(x)\phi(x)$; classically $f$ usually has the form $\psi(h(x))$, where $h$ is a regular function and $\psi$ is the additive character. Or we can treat definable functions $F : \Omega \to \mathcal{R}$ (Lebesgue style), and evaluation $\int_{\omega \in \Omega} F(\omega)$. We will work with the latter. Given this, to reconstruct a Riemann style integral, given $f : X \to \Omega$, and an $\mathcal{R}$-valued volume form $\phi$ on $X$, let

$$F(\omega) = \int_{f^{-1}(\omega)} \phi(x)$$

Then we can define

$$\int_X f(x)\phi(x) = \int_{\omega \in \Omega} \omega F(\omega)$$

It thus suffices to define the integral of a definable function on $\Omega$. Such a function can be interpreted as an $\mathcal{M}$-invariant function on $\text{VF}$. We impose one rule (cancellation): the integral of a function that is constant on each $\mathcal{O}$-class equals zero. The integral is a homomorphism on the group of $\mathcal{M}$-invariant functions $\text{VF} \to \mathcal{R}$, vanishing on the $\mathcal{O}$-invariant ones. We give a full description of the quotient group, showing that the universal homomorphism of this type factors through a similar group on the residue field.

Recall the group $\text{Fn}(V, \mathcal{R})$ of §2.2.1. We will not need to refer to the dimension grading explicitly.

If $V$ is a definable group, $V$ acts on on $\text{Fn}(V, \mathcal{R})$ by translation.

**Definition 11.1.** For a definable subgroup $W$ of $V$, let $\text{Fn}(V, \mathcal{R})^W$ be the set of $W$-invariant elements of $\text{Fn}(V, \mathcal{R})$: they are represented by a definable $X$, such that if $t \in W$ and $a \in V$ then $X[a], X[a + t]$ represent the same class in $\mathbb{K}(\text{VF}_{a,t})[n]$. 

**Lemma 11.2.** An element of $Fn(VF, R)^M$ can be represented by an $M$-invariant $X \subseteq (VF \times \ast)$.

**Proof.** Let $Y \in D_{VR}^V$ represent an element of $Fn(VF, R)^M$. So each fiber $Y_a \in D^{RV}$. By Lemma 3.52, for $a \in VF/M$ one can find $Y'_a \in D^{RV}$ such that for some $a \in VF$ with $a + M = a$, $Y_a = Y'_a$. As in Lemma 2.3 there exists $Y' \in R_{VF/M}$ such that $Y'_a$ to be the fiber of $Y'$ over $a$. Pulling back to VF gives the required $M$-invariant representative. \hfill $\square$

Since the equivalence is defined in terms of effective isomorphism, Definition 8.2, it is clear that two elements of $D_{\Omega}$ are equivalent iff the corresponding pullbacks to $Fn(VF, R)^M$ are equivalent.

The groups $Fn(VF, R)^M$ and $Fn(VF/M, R)$ can thus be identified.

Note that effective isomorphism agrees with pointwise isomorphism for $Fn(VF, R)^M$, but not for $Fn(VF/M, R)$.

The group we seek to describe is $A = A_T = Fn(VF, R)^M/Fn(VF, R)^Q$. The quotient corresponds to the cancellation rule discussed earlier.

Let $Fn(k, R)$ be the Grothendieck group of functions $k \to R$, with addition induced from $R$.

Let $C = R[\Omega]$ be the ring of definable functions $\Omega \to R$ with finite support, convolution product.

**Remark** $C$ embeds into the Galois-invariant elements of the abstract group ring $R_T[\Omega_T]$, where $T = T_{ad}(\emptyset)$.

The additive group $k = \emptyset/M$ is a subgroup of $\Omega = VF/M$, and so acts on $\Omega$ by translation. It also acts naturally on $Fn(k, R)$. This gives two actions on $Fn(k, C) = Fn(k, R)[\Omega]$. Let $Fn(k, C)_k$ denote the coinvariants with respect to the anti-diagonal action, i.e. the largest quotient on which the two actions coincide.

In general, the upper index denotes invariants, the lower index co-invariants.

$Fn(VF, R)$ is the ring of definable functions from $VF$ to $R$. $Fn(k, R)$ is the ring of definable functions from $k$ to $R$. $Fn(k, C)$ is the ring of definable functions from $k$ to $C$; equivalently, it is the set of Galois-invariant elements of the group ring $Fn(k, R)[\Omega]$.

The action of $k$ on $Fn(k, C)$ is by translation on $k$, and negative translation on $\Omega$ and hence on $C$. The term $\langle Const \rangle$ refers to the image of the constant functions of $Fn(k, C)$ in $Fn(k, C)_k$ (it is isomorphic to $\langle C/k \rangle$).

**Theorem 11.3.** There exists a canonical isomorphism $Fn(k, C)_k/\langle Const \rangle \cong Fn(VF, R)^M/Fn(VF, R)^Q$.

**Proof.** Let $A_{fin}$ be the subring of $Fn(VF, R)^M$ consisting of functions represented by elements of $Fn(VF, D)^M$ whose support projects to a finite subset of $VF/0$.

A definable function on $k$ can be viewed as an $M$-invariant function on $\emptyset$; this gives

\begin{equation}
Fn(k, R) \cong Fn(\emptyset, R)^M
\end{equation}

On the other hand we can define a homomorphism

\begin{equation}
Fn(\emptyset, R)^M[\Omega] \to A_{fin} : \sum_{\omega \in W} a(\omega)\omega \mapsto \sum_{\omega \in W} a(\omega)\omega
\end{equation}

where $W$ is a finite $A$-definable subset of $\Omega$, $a : W \to Fn(\emptyset, R)^M$ is an $A$-definable function, (so that $\sum_{\omega \in W} a(\omega)\omega$ is a typical element of the group ring $Fn(\emptyset, R)^M[\Omega]$), and $b_\omega$ is the translation of $b$ by $\omega$, i.e. $b_\omega(x) = b(x - \omega)$. 

(18) is surjective: let \( f \in A_{fin} \) be represented by \( F \), with support \( Z \), a finite union of translates of \( \emptyset \). By Lemma 3.39 there exists a finite definable set \( W \), meeting each ball of \( Z \) in a unique point. Define \( a : W \to Fn(\emptyset, \mathcal{R})^M \) by
\[
a(\omega) = (f|\omega + 0)_{\omega}.
\]
Then (18) maps \( \sum a(\omega)\omega \) to \( f \).

The kernel of (18) is the equalizer of the two actions of \( k \). Composing with (17) we obtain an isomorphism \( (Fn(k, \mathcal{R})[\Omega])_k \overset{\sim}{\to} A_{fin} \), or equivalently
\[
(19) \quad Fn(k, \mathcal{C})_k \overset{\sim}{\to} A_{fin}
\]

The last ingredient is the homomorphism
\[
A_{fin} \to \mathcal{A}
\]
We need to show that it is surjective, and to describe the kernel.

Using the representation \( D \) of elements of \( \mathcal{R} \) by RV-data, An element of \( A \) is is represented by an \( M \)-invariant definable \( W \subset VF \times RV^* \).

By Lemma 3.37, for each coset \( C \) of \( \emptyset \) in \( VF \) apart from a finite number, \( W \cap (C \times RV^{n+1}) \) is invariant under translation of the first coordinate by elements of \( \emptyset \). Thus \( W \) is the disjoint sum of an \( \emptyset \)-invariant set \( W' \) and a set \( W'' \subset VF \times RV^* \) projecting to a finite union \( Z \) of cosets of \( \emptyset \) in \( VF \), i.e. representing a function in \( A_{fin} \).

Clearly \( W' \times_{RV^*} VF^* \) lies in \( Fn(VF, \mathcal{R})[\emptyset] \).

Thus (20) is surjective; the kernel is \( A_{fin}^0 \). Composing (19),(20) we obtain an isomorphism
\[
\mathcal{A} \overset{\sim}{\to} (Fn(k, \mathcal{R})[\Omega])_k/(\text{Const})
\]

Using the identification \( Fn(k, \mathcal{R})[\emptyset] \simeq Fn(k, \mathcal{C}) \), the theorem follows. 

\[ \square \]

Note that \( Fn(k, \mathcal{C})_k \simeq \mathcal{C} \), via \( Fn(k, \mathcal{C}) \simeq Fn(k \times \emptyset, \mathcal{R})_{fin} \).

11.1. Definable distributions. \( \mathcal{R} \) is graded by dimension (VF-presentation) or ambient dimension (RV-presentation.) Write \( \mathcal{R} = \oplus_{n \geq 0} \mathcal{R}[n] \).

Let \( \mathcal{R}_{df} \) be the dimension-free version: first form the localization \( \mathcal{R}[[0]^{-1}] \), where \( [0] \) is the class of the point \( 1 \in RV \), as an element of \( RV[1] \). Equivalently, \( [0]^n \) is the volume of the open \( n \)-dimensional polydisc \( 0^n \). Let \( \mathcal{R}_{df} \) be the zero-dimensional component of this localization. Similarly define \( \mathcal{C}_{df} \); so that \( \mathcal{C}_{df} = \mathcal{R}_{df}[[0]] \). We can also define \( K_+(D)_{df} \), and check that the groupification is \( \mathcal{R}_{df} \).

Given \( a = (a_1, \ldots, a_n) \in VF^n \) and \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \Gamma^n \), let \( B(a, \gamma) = \prod_{i=1}^n B(a_i, \gamma_i) \), where \( B(a_i, \gamma_i) = \{ c \in VF : \text{val}(c - a_i) > \gamma_i \} \). Call \( B(a, \gamma) \) an open poly-disc of dimensions \( \gamma \). If \( \gamma \in \Gamma \), let \( B(a, \gamma) = B(a, \gamma_1, \ldots, \gamma_n) \) (the open cube of side \( \gamma \).)

Note that \( [B(0, \gamma)] \) is invertible in \( \mathcal{R}_{df} \), in each dimension. In particular in dimension 1, \( [B(0, \gamma)] [B(0, -\gamma)] = [0]^2 \). Note also: \( [B(a, \gamma)] = _a [B(0, \gamma)] \).

We proceed to define integrals of definable functions.

Let \( U \) be a bounded definable subset of \( VF^n \). A definable function \( f : U \to K_+(D)_{df} \) has the form \( [0]^{-m} F \), where \( F : U \to K_+D[m] \) is a definable function, represented by some \( \bar{F} \in D[m + n]_U \). In case \( \bar{F} \) can be taken bounded, define
\[
\int_U f = [0]^{-m+n} [F]_{n+m}
\]
We say that $f$ is \textit{boundedly represented} in this case.

In particular $\text{vol}(U) = \int_U 1 = [0]^{n-m}[U]_m$ is treated as a pure number now, without dimension units. (Check independence of the choices.)

This extends by linearity to $\int_U f$ for $f : U \to \mathcal{R}_g$, provided $f$ can be expressed as the difference of two boundedly represented functions $U \to K_+(\mathcal{D})_g$.

We now note that averaging twice, with appropriate weighting, is the same as doing it once. The function $\gamma'$ in the lemmas below corresponds to a part of $\Gamma$ into cubes; $\gamma'(u)$ is the side of the cube around $u \in U$.

**Lemma 11.4.** Let $U$ be a bounded open subset of $VF^n$, $f$ a boundedly represented function on $U$. Let $\gamma' : U \to \Gamma$ be a definable function such that if $u \in U$ and $u' \in B(u, \gamma'(u))$ then $u' \in U$ and $\gamma'(u') = \gamma'(u)$. Then

$$
\int_U f = \int_U [\text{vol}(B(u, \gamma'(u)))^{-1}] \int_{B(u, \gamma'(u))} f
$$

**Proof.** Let $f = [0]_1^{-m}F$, where $F : U \to K_+ \mathcal{D}[m]$ is bounded. We have $\text{vol}(B(u, \gamma')) = [0]_1^{-m}[-\gamma(u)]^n$ so

$$
\text{vol}(B(u, \gamma'))^{-1} = [0]_1^n[-\gamma'(u)]^{-n} = [0]_1^n[-\gamma'(u)]^n
$$

Thus, multiplying by $[0]_1^{n+m}$, we have to show

$$
[0]_1^n[F] = [-\gamma'(u)]^{-n}[[u, u', z] : u \in U, u' \in B(u, \gamma'(u)), (u', z) \in F]
$$

Now $u' \in B(u, \gamma'(u))$ iff $u \in B(u', \gamma'(u'))$. Applying the measure preserving bijection $(u, u', z) \mapsto (u - u', u', z)$ we see that the $[[u, u', z] : u \in U, u' \in B(u, \gamma'(u)), (u', z) \in F] = [\gamma']^{-1}[[u', z] : (u', z) \in F]$ so the equality is clear. \hfill $\Box$

We now define the integral of definable functions into $\mathcal{E}_g$. By definition, such a function is a finite sum of products $fg$, with $f \in Fn(U, \mathcal{R}_g)$ and $g \in Fn(U, \mathcal{E}_g)$. Define

$$
\int_U fg = \int_{\omega \in \Omega} \omega \int_{g^{-1}\omega(f)} f
$$

and extend by linearity.

Note that this is defined as soon as $g$ is boundedly represented. (Again, check independence of choices.)

**Definition 11.5.** A definable distribution on an open $U \subseteq VF^n$ is a definable function $\vartheta : U \times \Gamma \to \mathcal{E}_g$, such that $\vartheta(a, \gamma) = \vartheta(a', \gamma)$ if $B(a, \gamma) = B(a', \gamma)$, and whenever $\gamma' > \gamma$ in each coordinate,

$$
\vartheta(h, \gamma) = \int_{u \in B(h, \gamma)} \text{vol}(B(0, \gamma'))^{-1} \vartheta(u, \gamma')
$$

As in Lemma 11.2, the invariance condition means that $\vartheta$ can be viewed as a function on open polydiscs, and we will view it this way below.

If $\vartheta$ takes values in $\mathcal{R}_g$, we say it is $\mathcal{R}_g$-valued. By definition, $\vartheta$ can be written as a finite sum $\sum \omega_i \vartheta_i$, where $\vartheta_i$ is an $\mathcal{R}_g$-valued function; in fact $\vartheta_i$ is an $\mathcal{R}_d$-valued distribution.

We wish to strengthen the definition of a distribution so as to apply to sub-polydiscs of variable size. For this we need a preliminary lemma.

**Lemma 11.6.** Let $U = B(a, \gamma)$ be a polydisc. Let $\gamma' : B(a, \gamma) \to \Gamma$ be a definable function such that $\gamma'(u) = \gamma'(u)$ for $u' \in B(u, \gamma'(u))$. Then $\gamma'$ is bounded on $U$.

**Proof.** suppose for contradiction that $\gamma'$ is not bounded on $B(a, \gamma)$, i.e.

$$(\forall \delta \in \Gamma)(\exists u \in B(a, \gamma))(\gamma'(u) > \delta)$$
This will not change if we add a generic element of $\Gamma$ to the base, so we may assume $\Gamma(\text{dcl}(\emptyset)) \neq (0)$. By Lemma 3.31, there exists a resolved structure with the same RV-part as $< \emptyset>$; hence we may assume $T$ is resolved. By §6.0.1 any VF-generated structure is resolved. By Lemma 3.49, for any $M \models T$ and $c \in \text{VF}(M)$, $\text{acl}(c)$ is an elementary submodel of $M$. Consider $c$ with $\text{val}(c) \models p_0$, where $p_0$ is the generic type at $\infty$ of elements of $\Gamma$, i.e. $p_0[A] = \{ x > \delta : \delta \in \Gamma(A) \}$.

Since

$$\text{acl}(c) = (\forall \delta \in \Gamma)(\exists u \in B(a, \gamma))(\gamma'(u) > \delta)$$

there exists $e \in \text{acl}(c)$ with $e \in B(a, \gamma)$ and $\gamma'(e) > \text{val}(c)$. By Lemma 5.12, there exists $e_0 \in \text{acl}(\emptyset)$ such that $(c, e) \rightarrow (0, e_0)$. In particular $e_0 \in B(a, \gamma)$. But then since $e \rightarrow e_0$ and $\gamma'(e_0) \in \Gamma(\text{acl}(\emptyset))$ we have $e \in B(e_0, \gamma'(e_0))$. So $\gamma'(e) = \gamma'(e_0)$. But then $\gamma'(e_0) > \text{val}(c)$, contradicting the choice of $c$. \hfill \Box

**Lemma 11.7.** (1) Let $\bar{c} : U \times \Gamma \rightarrow \mathbb{C}_{df}$ be a definable distribution. Let $\gamma' : U \rightarrow \Gamma$ be a definable function with $\gamma'(u) > \gamma$, such that $\gamma'(u') = \gamma'(u)$ for $u' \in B(u, \gamma'(u))$. Then

$$\bar{c}(b, \gamma) = \int_{u \in B(b, \gamma)} \text{vol}(B(0, \gamma'(u)))^{-1} \bar{c}(u, \gamma'(u))$$

(2) Let $\bar{c}_1, \bar{c}_2$ be definable distributions on $U$ such that for any $x \in U$, for all large enough $\gamma \in \Gamma$, for any $y \in B(x, \gamma)$ and any $\gamma' > \gamma$, $\bar{c}_1(B(y, \gamma')) = \bar{c}_2(B(y, \gamma'))$. Then $\bar{c}_1 = \bar{c}_2$.

**Proof.** (1) To prove (21), fix $b, \gamma$. We may assume $U = B(b, \gamma)$. Using Lemma 11.6, pick a constant $\gamma''$ with $\gamma'' > \gamma'(u)$ and compare the values of $\bar{c}(b, \gamma''(u))$ and $\bar{c}(u, \gamma''(u))$, and compare the integrals using Lemma 11.4.

(3) Define $\gamma'(u)$ to be the smallest $\gamma'$ such that for all $\gamma'' > \gamma'$ and all $y \in B(u, \gamma')$, $\bar{c}_1(B(y, \gamma''(u))) = \bar{c}_2(B(y, \gamma''(u)))$. It is clear that $\gamma'(u') = \gamma'(u)$ for $u' \in B(u, \gamma'(u))$. (21) gives the same integral formula for $\bar{c}_1(b, \gamma)$ and $\bar{c}_2(b, \gamma)$.

Let $\bar{c}$ be a definable distribution, and $U$ an arbitrary bounded open set. We can define $\bar{c}(U)$ as follows. For any $x \in U$, let $\rho(x, U)$ be the smallest $\rho \in \Gamma$ such that $B(x, \rho) \subseteq U$. Let $B(x, U) = B(x, \rho(x, U))$; this is the largest open cube around $x$ contained in $U$. Note that two such cubes $B(x, U), B(x', U)$ are disjoint or equal. Define

$$\bar{c}(U) = \int_{x \in U} \text{vol}(B(x, U))^{-1} \bar{c}(x, \rho(x, U))$$

More generally, if $h$ is a locally constant function on $\text{VF}^n$ into $\mathbb{R}_{df}$ with bounded support, we can define

$$\bar{c}(h) = \int_{x \in \text{VF}^n} h(x)[B(x, h)]^{-1} \bar{c}(x, \rho(x, U))$$

where now $B(x, h) = B(x, \rho(x, U))$ is the largest open cube around $x$ on which $h$ is constant.

**Proposition 11.8.** Let $\bar{c}$ be a definable distribution. Then there exists a definable open set $G \subseteq \text{VF}^n$ whose complement $Z$ has dimension $< n$, and a definable function $g : G \rightarrow \mathbb{C}_{df}$ such that for any polydisc $U \subseteq G$

$$\bar{c}(U) = \int_{U} g$$
Proof. Since $\vartheta$ is a finite sum of $\mathcal{R}_{d'}$-valued distributions, we may assume it is $\mathcal{R}_{d'}$-valued. Given $a \in \mathrm{VF}^n$, we have a function $\alpha_a : \Gamma \to \mathcal{R}_{d'}$ defined by $\alpha_a(\rho) = \vartheta(B(a, \rho))$. Using the RV-description of $\mathcal{R}$, and the stable embeddedness of $\mathrm{RV} \cup \Gamma$, we see that $\alpha_a$ has a canonical code $c(a) \in (\mathrm{RV} \cup \Gamma)^*$.

Let $G$ be the union of all polydiscs $W$ such that $c$ is constant on $W$. Let $Z = \mathrm{VF}^n \setminus G$. By Lemma 5.13, $\dim(Z) < n$.

**Claim** Let $W$ be a polydisc such that $c$ is constant on $W$. Then for some $r \in \mathcal{R}_{d'}$, for any polydisc $U = B(a, \rho) \subseteq W$ $\vartheta(a, \rho) = r \cdot \mathrm{vol}(U)$.

Proof. Since $c$ is constant on $W$, for some function $\delta$, all $\rho$ and all $b \in W$ with $B(w, \rho) \subseteq W$, we have $\vartheta(B(w, \rho)) = \delta(\rho)$. By definition of a distribution we have, for any $a \in W$

$$\delta(\rho) \cdot \mathrm{vol}(B(a, \rho')) = \vartheta(B(a, \rho'))$$

Now $\mathrm{vol}(B(a, \rho)) = \vartheta(0, \rho)$. So $\delta(\rho) \cdot \vartheta(0, \rho') = \vartheta(B(0, \rho)) \cdot \delta(\rho')$. Since this holds for any $a \in W$, by Proposition 3.51 we have

$$\delta(\rho) \cdot \vartheta(B(0, \rho')) = \vartheta(B(0, \rho)) \cdot \delta(\rho')$$

So $\delta(\rho) / \vartheta(B(0, \rho)) = r$ is constant. The Claim follows.

The Proposition follows too using Lemma 11.7. \qed

11.2. Fourier transform. Let $\psi$ be the tautological projection $K \to K/\mathcal{M} = \Omega$.

Let $g : \mathrm{VF}^n \to \mathcal{C}_{d'}$ be a definable function, bounded on bounded subsets of $\mathrm{VF}^n$. Define a function $\mathcal{F}(g)$ by

$$\mathcal{F}(g)(U) = \int_{y \in \mathrm{VF}} g(y) \left( \int_{x \in U} \psi(x \cdot y) \right)$$

This makes sense since for a given $U$, $(\int_{x \in U} \psi(x \cdot y))$ vanishes for $y$ outside a certain polydisc (with sides inverse to $U$.) Moreover,

**Lemma 11.9.** $\mathcal{F}(g)$ is a definable distribution.

Proof. This follows from Fubini, Lemma 11.4, and chasing the definitions. \qed

**Corollary 11.10.** Fix integers $n, d$. For all local fields $L$ of sufficiently large residue characteristic, for any polynomial $G \in L[X_1, \ldots, X_n]$ of degree $d$, there exists a proper variety $V_G$ of $L^n$ such that $\mathcal{F}(G)$ agrees with a locally constant function outside $V_G$.

Proof. By Lemma 11.9 and Lemma 11.8. \qed

See [4] for the real case.

12. Expansions and rational points over Henselian fields

We have worked everywhere with the geometry of algebraically closed valued fields, or more generally of $\mathbb{T}$, but at a geometric level; all objects and morphisms can be lifted to the algebraic closure, and quantifiers are interpreted there.

For many purposes, we believe this is the right framework. It includes for instance Igusa integrals $\int_{x \in X(F)} \left| f(x) \right|^s$, and we will show in a sequel how to interpret in it some constructions of representation theory. See also [21].

In other situations, however, one wishes to integrate definable sets over Henselian fields rather than only constructible sets; and to have a change of variable formula for definable maps, as obtained by Denef-Loeser and Cluckers-Loeser (cf. [7]). It turns out that our formalism lends
itself immediately to this generalization; we explain in this section how to recover it. The point is that an arbitrary definable set is an RV-union of constructible ones, and the integration theory commutes with RV-unions.

We will consider $F$ that admit quantifier elimination in a language $L^+$ obtained from the language of $T$ by adding relations to RV only. For example, if $F = Th(\mathbb{C}(x))$, $F$ has quantifier elimination in a language expanded with names $D_n$ for subgroups of $\Gamma$ (with $D_n(F) = n\Gamma(F)$).

There are two steps in moving from $F^{alg}$ to $F$. We will try to clarify the situation by taking them one at a time. The two steps are to restrict the points to a smaller set (the $F$-rational points), and the enlarge the language to a larger one (with enough relation symbols for $F$-quantifier elimination.) We will take these steps in the reverse order. In §12.1 we show how to extend the results of this paper to expansions of the language in the RV sorts, and in §12.3 how to pass to sets of rational points over a Hensel field.

The reader who wishes to restrict attention to constructible integrals (still taking rational points) may skip §12.1, taking $T^+ = T$ in §12.3. In this case one still has a change of variable formula for constructible change of variable, but not for definable change of variable. An advantage is that the the target ring correspondingly involves the Grothendieck group of constructible sets and maps rather than definable ones, which sometimes has more faithful information; cf. Example 12.12.

12.1. Expansions of the RV sort. Let $T$ be $V$-minimal.

Let $T^+$ be an expansion of $T$ obtained by adding relations to RV. We assume that every $M \models T$ embeds into the restriction to the language of $T$ of some $N \models T^+$ (as $T$ is complete, this is actually automatic.) By adding some more basic relations, without changing the class of definable relations, we may assume $T^+$ eliminates RV-quantifiers. As $T$ eliminates field quantifiers, and $T^+$ has no new atomic formulas with $VF$ variables, $T^+$ eliminates $V$-quantifiers too, hence all quantifiers.

For instance $T^+$ may include a name for a subfield of the residue field (say, pseudo-finite) or the angular coefficients the the Denef-Pas language (where RV is split). Write $+$-definable for $T^+$-definable; similarly $tp_+$ will denote the type in $T^+$; etc. The unqualified words formula, type, definable closure will refer to quantifier-free formulas of $T$.

**Lemma 12.1.** Let $M \models T^+$. Let $A$ be a substructure of $M$, $c \in M$, $B = A(c) \cap RV$.

1. $tp(c/A \cup B) \cup T^+_A \cap B$ implies $tp_+(c/A \cup B)$,
2. Assume $c$ is $T^+_A$-definable. Then $c \in dcl(A, b)$ for some $b \in A(c) \cap RV$.

**Proof.** (1) This follows immediately from the quantifier elimination for $T^+$. Indeed let $\phi(x) \in tp_+(c/A \cup B)$. Then $\phi$ is a Boolean combination of atomic formulas, and it is sufficient to consider the case of $\phi$ atomic, or the negation of an atomic formula. Now since any basic function $VF^n \to VF$ is already in the language of $T$, every basic function of the language of $T^+$ denoting a function $VF^n \to VF$ factors through a $T$-definable function into RV. Hence the same is true for all terms (compositions of basic functions). And any basic relation is either the equality relation on RV, or else a relation between variables of RV. If $\phi$ is an equality or inequality between $f(x), g(x)$, it is already in $tp(c/A)$. Now suppose $\phi$ is a relation $R(f_1(x), \ldots, f_n(x))$ between elements of RV. Since $B(c) \cap RV \subseteq B$, the formula $f_i(x) = b_i$ lies in $tp(c/A \cup B)$ for some $b_i \in B$. On the other hand $R(b_1, \ldots, b_n)$ is part of $T^+_A$. These formulas together imply $R(f_1(x), \ldots, f_n(x))$.

2. We must show that $c \in dcl(A \cup B)$. Let $p = tp(c/A \cup B)$. By (1), $p$ generates a complete type of $T^+_A \cap B$. Since this is the type of $c$ and $c$ is $T^+_A$-definable, and since any model of $T$ embeds into a model of $T^+$, $p$ has a unique solution solution in any model of $T$. Thus $c \in dcl(A \cup B)$. 

We will now see that any $T^+$-definable bijection decomposes into $T$-bijections, and bijections of the form $x \mapsto (x, j(g(x)))$ where $g$ is a $T$-definable map into $RV^m$ and $j$ is a $T^+$-definable map on $RV$.

**Corollary 12.2.** (1) Let $P$ be a $T^+$-definable set. There exist $T$-definable $f : \tilde{P} \to RV^*$ and a $T^+$-definable $Q \subseteq RV^*$ such that $P = f^{-1}Q$.

(2) Let $P_1, P_2$ be $T^+$-definable sets, and let $F : P_1 \to P_2$ be a $T^+$-definable bijection. Then there exist $g_i : \tilde{P}_i \to R_i \subseteq RV^m$, $R \subseteq RV^m$, $h_i : R \to R_i$, and a bijection $H : \tilde{P}_1 \times g_{1, h_1} R \to \tilde{P}_2 \times g_{2, h_2} R$ over $R$, all $T^+$-definable, and $T^+$-definable $Q_i \subseteq R_i$, $Q \subseteq R$, and $j_i : Q_i \to Q$ such that $P_i = g_i^{-1}Q_i$, $h_i j_i = Id_{Q_i}$, and for $x \in P_1$

\[ (\circ) \quad j_i g_i(x) = j_2 g_2(F(x)) = j(x), \quad \text{and} \quad H(x, j(x)) = (F(x), j(x)) \]

Moreover if $P_1 \subseteq VF^n \times RV^m$ projects finite-to-one to $VF^n$, then $R \to R_i$ is finite-to-one.

**Proof.** (1) Let $\mathcal{F}$ be the family of all $T$-definable functions $f : W \to RV^m$ where $W$ is a definable set.

**Claim** If $tp(c) = tp(d)$ and $f(c) = f(d)$ for all $f \in \mathcal{F}$ with $c, d \in \text{dom}(f)$, then $c \in P \iff d \in P$.

**Proof.** We have $tp(c, f(c)) = tp(d, f(d)) = tp(d, f(c))$, so $tp(c/f(c)) = tp(d/f(c))$ for all $f \in \mathcal{F}$ with $c \in \text{dom}(f)$, and thus $tp(c/B) = tp(d/B)$, where $B = A(c) \cap RV$. It follows that $tp_+(c) = tp_+(d)$, and in particular $c \in P \iff d \in P$.

By compactness, there are $(f_i, W_i)_{i=1}^{m} \in \mathcal{F}$ such that if $c \in W_i \iff d \in W_i$ and $f_i(c) = f_i(d)$ whenever $c, d \in W_i$, then $c \in P \iff d \in P$. Let $P = \cup_i W_i$, and extend $f_i$ to $\tilde{P}$ by $f_i(x) = \infty$ if $x \notin W_i$. Let $f(x) = (f_1(x), \ldots, f_m(x))$. Letting $\tilde{P} = \cup_i W_i$ and $Q = f(\tilde{P})$, (1) follows.

For (2), consider first a $T^+$-type $p = tp_+(c_1)$, $c_1 \in P_1$. Let $c_2 = F(c_1)$. Using Lemma 3.48, there exists $g_i^* \in \mathcal{F}$ such that $e_1 = g_i^*(c_i)$ generates $\text{dcl}(c_i) \cap RV$. It follows as in Lemma 12.1 (1) that $e_i$ generates $\text{dcl}(c_i) \cap RV$. Let $e$ generate $\text{dcl}(c_1, c_2) \cap RV$; we have $e_i = h_i(e)$ for appropriate $T$-definable $h_i^*$. Note $\text{dcl}(c_1) = \text{dcl}(c_2)$, and so $e \in \text{dcl}(c_i)$. Now quantifier elimination for $T^+$ implies the stable embeddedness of RV, in the same way as for ACVF (cf. §2.1.5.) By Lemma 2.9 $tp_+(c_i/e_i)$ implies $tp_+(c_i/RV)$; in particular since $e \in \text{dcl}(c_1, c_2 \in \text{dcl}(c_i, e)$ for some $T^+$-definable $j_i^*$. By Lemma 12.1 (2) over $\text{dcl}(c_1)$, $c_2 \in \text{dcl}(c_1, e)$; similarly $c_1 \in \text{dcl}(c_2, e)$; so there exists a $T$-definable invertible $H^p$ with $H^{p}(c_1, e) = (c_2, e)$. The equations $(\circ)$ have been shown to hold on $p$. Now $g_i$ extends to a $T$-definable function $g_i : \tilde{P}_i \to R_i$. By compactness $(\circ)$ holds on some definable neighborhood of $p$; and by (1) this neighborhood can be taken to have the form $g_i^{-1}Q_i$ for some $Q_i$. Finitely many such neighborhoods cover $P_1$, and the data can be sewed together as in (1). We thus find $\tilde{P}_1, R, R_1, R_2, g_1, g_2, h_1, h_2, H, Q_1, j_1, j_2$ such that $h_{i j_i}(x) = x$ and $(\circ)$ holds on $g_i^{-1}Q_i = P_i$. Let $Q_2 = h_{j_1}Q_1$; it follows that $P_2 = F(R_1) = g_2^{-1}Q_2$.

To prove the last point, since $c_2 \in \text{dcl}(c_1, e)$ we have (Lemma 3.41) $c_2 \in \text{acl}(c_1)$. But $e \in \text{dcl}(c_1, c_2)$ so $e \in \text{acl}(\text{dcl}(c_1))$; and as $e \in RV^m$ for some $m$, $e \in \text{acl}(\text{dcl}(c_1))$. □

Let $VF^+$ be the category of $+$-definable subsets of varieties over $VF \cap \text{dcl}(\emptyset)$, and $+$-definable maps. Define effective isomorphism as in Definition 8.2; let $K_{+\text{eff}}$ denote the Grothendieck group of effective isomorphism classes, and let $[X]$ be the class of $X$.

Let $RV^{+\text{[\ast]}}$ be the category of pairs $(Y, f)$, where $Y$ is a $+$-definable subset of $X$ for some $(X, f) \in \text{Ob} RV^{+\text{[\ast]}}$ (Definition 3.66). A morphism $(Y, f) \to (Y', f')$ is a definable bijection $h : Y \to Y'$ such that $f'(h(y)) \in \text{acl}(f(y))$ for $y \in Y$. 
Let $K_+(RV^+[s])$ be the Grothendieck semi-group of isomorphisms classes of $RV^+$; let $I_{sp}$ be the congruence generated by $(J,1)$ where $J = \{1\}_0 + [RV^{>0}]_1$.

**Proposition 12.3.** There exists a canonical surjective homomorphism of Grothendieck semi-groups

$$\mathcal{P} : K_+(VF^+[s]) \to K_+(RV^+[s])/I_{sp}$$

determined by:

$$\mathcal{P}[X] = [W]/I_{sp} \iff [X] = [LW]$$

**Proof.** We have to show:

(i) any element of $K_+(VF^+)$ is effectively isomorphic to one of the form $[LW]$;

(ii) if $[LW_1] = [LW_2]$ then $([W_1],[W_2]) \in I_{sp}$.

(i) By Corollary 12.2 (1), a typical element of $K_+(VF^+)$ is represented by $P = f^{-1}Q$, where $Q \subseteq RV^*$ is $T^+$-definable, $\tilde{\mathcal{P}} : \tilde{P} \to RV^*$ is $T$-definable. For any $a \in RV^*$, $f^{-1}(a)$ is $T_0$-definable, and $[f^{-1}(a)] = [LC_a]$ where $[C_a] = [f^{-1}(a)]$. Since $L$ commutes with $RV$-disjoint unions, it follows that $[P] = [LW]$ where $W = \bigcup_{a \in Q} C_a$.

(ii) Assume $[LW_1] = [LW_2]$. By Proposition 3.51, the base can be enlarged so as to be made effective, without change to $RV$; thus to show that $([W_1],[W_2]) \in I_{sp}$ we may assume $LW_1, LW_2$ are isomorphic. Let $f : LW_1 \to LW_2$ be an isomorphism. Let $P_i = LW_i$ and let $\tilde{P}_i, R_i, r_i, h_i, R, H, Q, Q_i, j_i$ be as in Corollary 12.2 (2).

Since $P_i = g_i^{-1}Q_i = LW_i$, the maximal $\sim$-invariant subset of $\tilde{P}_i$ contains $P_i$, so we may assume $\tilde{P}_i$ is $\sim$-invariant; in other words $\tilde{P}_i = LW_i$ for some $T$-definable $W_i \in RV[*,Y]$ containing $W_i$.

By Lemma 7.8, there exists a special bijection $\sigma : LW_1^* \to LW_i$ such that $g_i \circ \sigma$ factors through $\rho_i$, i.e. for some $\varepsilon_i : \tilde{W}_1^* \to R_i$ we have $g_i \circ \sigma = \varepsilon_i \circ \rho$ on $\tilde{W}_1^*$. Let $W_1^*$ be the pullback of $W_i$ to $\tilde{W}_1^*$, so that $\sigma(LW_1^*) = LW_i = P_i$. Then $([W_1],[W_1^*]) \in I_{sp}$, so it suffices to show that $([W_1^*], [W_2^*]) \in I_{sp}$ since $P_i = g_i^{-1}Q_i$, we have $W_1^* = \sigma^{-1}Q_i$.

For $c \in R_i$, let $\tilde{P}_i(c) = \sigma^{-1}g_i^{-1}(h_i(c))$, $\tilde{W}_i(c) = g_i^{-1}(h_i(c))$. Then $\tilde{P}_i(c) = \tilde{W}_i(c)$. Now $H$ induces a bijection $\tilde{P}_i(c) \to \tilde{P}_2(c)$. Thus by Proposition 7.25, $([\tilde{W}_1(c)], [\tilde{W}_2(c)]) \in I_{sp}$. In particular this is true for $c \in Q$; now $h_i : Q \to Q_i$ is a bijection, and $W_i^* = \cup_{c \in Q} W_i(c)$. Thus $([W_1^*], [W_2^*]) \in I_{sp}$. \hfill $\square$

**Remark** Since the structure on $RV$ in $T^+$ is arbitrary, we cannot expect the homomorphism of Corollary 12.3 to be injective. We could make it so tautologically by modifying the category $RV^+$, taking only liftable morphisms, i.e. those that lift to $VF$; we then obtain an isomorphism. In specific cases it may be possible to check that all morphisms are liftable.

### 12.2. Transitivity

**Motivation.** Consider a tower of valued fields, such as $C \leq \mathcal{C}((s)) \leq \mathcal{C}((s))(\{(t)\})$. Given a definable set over $\mathcal{C}((s))(\{(t)\})$, we can integrate with respect to the $t$-valuation, obtaining data over $\mathcal{C}((s))$ and the value group. The $\mathcal{C}((s))$ can then be integrated with respect to the $s$-valuation. On the other hand, we can consider directly the $\mathbb{Z}^2$-valued valuation of $\mathcal{C}((s))(\{(t)\})$, and integrate so as to obtain an answer involving the Grothendieck group of varieties over $C$. We develop below the language for comparing these answers, and show that they coincide.

For simplicity we accept here a Denef-Pas splitting, i.e. we expand $RV$ so as to split the sequence $k^* \to RV^+ \to \Gamma$. Then $rv$ splits into two maps, $ac : VF^+ \to k^*$ and $val : VF^+ \to \Gamma$. Therefore...
This expansion of ACVF(0,0) is denoted ACVF\( ^{DP} \). Note that this falls under the framework of §12.1, as will the further expansions below.

Consider two expansions of ACVF\( ^{DP} \): (1) expand the residue field to have the structure of a valued field (itself a model of ACVF\( ^{DP} \)), (2) expand the value group to be a lexicographically ordered product of two ordered Abelian groups. Then (1),(2) yield bi-interpretable theories. In more detail:

First expansion: Rename the VF sort as VF\(_{21} \), the residue field as VF\(_{1} \), and the value group \( \Gamma_{1} \). VF\(_{1} \) carries a field structure; expand it to a model of ACVF\( ^{DP} \), with residue field \( F_{0} \) and value group \( \Gamma_{0} \). Let \( ac_{21}, val_{2} \) have their natural meanings.

Second expansion: Rename the VF-sort as VF\(_{20} \), the residue field as \( F_{0} \) and the value group as \( \Gamma_{20} \). Add a predicate \( \Gamma_{0} \) for a proper convex subgroup of \( \Gamma_{20} \), and a predicate \( \Gamma_{1} \) for a complementary subgroup, so that \( \Gamma_{20} \) is identified with the lexicographically ordered \( \Gamma_{0} \times \Gamma_{1} \).

**Lemma 12.4.** The two theories described above are bi-interpretable. A model of (1) can canonically be made into a model of (2) with the same class of definable relations; and vice versa.

**Proof.** Given (1), let VF\(_{20} \) = VF\(_{21} \) as fields. Define

\[
ac_{20} = ac_{10} \circ ac_{21}
\]

Let \( \Gamma_{20} = \Gamma_{1} \times \Gamma_{0} \), and define \( val_{20} : VF_{21}^{*} \rightarrow \Gamma_{20} \) by

\[
val_{20}(x) = (val_{21}(x), val_{10}(ac_{21}(x)))
\]

Conversely given (2), let VF\(_{21} \) = VF\(_{20} \) as fields;

\[
\mathcal{O}_{21} = \{x \in VF_{21} : (\exists t \in \Gamma_{0})(val_{20}(x) \geq t)\}
\]

\[
\mathcal{M}_{21} = \{x \in VF_{21} : (\forall t \in \Gamma_{0})(val_{20}(x) > t)\}
\]

VF\(_{1} \) = \( \mathcal{O}_{21} / \mathcal{M}_{21} \)

Let VF\(_{21} \) have the valued field structure with residue field VF\(_{1} \); note that the value group \( VF_{21}^{*} / \mathcal{O}_{21}^{*} \) can be identified with \( \Gamma_{1} \). Note that ker \( ac_{20} \supset 1 + \mathcal{M}_{21} \), so that factors through VF\(_{1}^{*} \), and define \( ac_{10}, ac_{21} \) so as to make (23) hold. Then define \( val_{21}, val_{10} \) so that (24) holds. \( \square \)

Let VF\(^{+} [*] \) denote the category of definable subsets of VF\(_{21} \), equivalently VF\(_{20} \), in the expansions (1) or (2). According to Proposition 12.3, and Lemma 2.11, we have canonical maps \( K_{+}(VF^{+}[*]) \rightarrow K_{+}(RV_{1}^{+}[*]) / I_{sp} \) and \( K_{+}(VF^{+}[*]) \rightarrow K_{+}(RV_{2}^{+}[*]) / I_{sp} \), where \( RV_{1}^{+}[*] \) denotes the expansion of RV according to (1),(2) respectively.

By Proposition 8.4 we have canonical maps:

\[
K_{+}(VF^{+}[*]) \rightarrow K_{+}(VF_{1}[*]) \circ K_{+}(\Gamma_{21}[*]) / I_{sp} \rightarrow (K_{+}(F_{0}) \circ K_{+}(\Gamma_{10})) \circ K_{+}(\Gamma_{21}) / I_{sp_{1}}
\]

for a certain congruence \( I_{sp_{1}} \). And on the other hand:

\[
K_{+}(VF^{+}[*]) \rightarrow K_{+}(F_{0}[*]) \circ K_{+}(\Gamma_{20}[*]) / I_{sp} = K_{+}(F_{0}[*]) \circ (K_{+}(\Gamma_{10}[*]) \circ K_{+}(\Gamma_{21}[*])) / I_{sp_{2}}
\]

For an appropriate \( I_{sp_{2}} \). The tensor products here are over \( \mathbb{Z} \), in each dimension separately.

Using transitivity of the tensor product we identify \( (K_{+}(F_{0}) \circ K_{+}(\Gamma_{10})) \circ K_{+}(\Gamma_{21}) \) with \( K_{+}(F_{0}[*]) \circ (K_{+}(\Gamma_{10}[*]) \circ K_{+}(\Gamma_{21}[*])) \). Then

**Theorem 12.5.** \( I_{sp_{1}}, I_{sp_{2}} \) are equal and the maps of (25),(26) coincide.
Proof. It suffices to show in the opposite direction that the compositions of maps induced by $L$

\[(27) \quad (K_+(F_0[*]) \otimes K_+(\Gamma_{10}[*])) \otimes K_+(\Gamma_{21}[*]) \to K_+(VF_1[*]) \otimes K_+(\Gamma_{21}[*]) \to K_+(VF^+[*])\]

\[(28) \quad K_+(F_0[*]) \otimes K_+(\Gamma_{10}[*]) \otimes K_+(\Gamma_{21}[*]) \to K_+(F_0[*]) \otimes K_+(\Gamma_{20}[*]) \to K_+(VF^+[*])\]

coincide. But this reduces by RV-additivity to the case of points, and by multiplicativity to the individual factors $F_0, \Gamma_{21}, \Gamma_{10}$, yielding to an obvious computation in each case. \hfill \Box

12.3. Rational points over a Henselian subfield: constructible sets and morphisms.

Let $\mathbb{T}$ be $\mathbb{V}$-minimal, and $\mathbb{T}^+$ an expansion of $\mathbb{T}$ in the RV sorts.

Let $F$ be an effective substructure of a model of $\mathbb{T}$. Thus $F = (F_{VF}, F_{RV})$, with $F_{VF}$ a field, and $rv(F_{VF}) = F_{RV}$; and, $F$ closed under definable functions of $\mathbb{T}$. For example, if $\mathbb{T} = \mathbb{T}^+ = ACVF(0,0)$, this is the case iff $F_{RV}$ is a Henselian field and $F_{RV} = F/N(F)$; any Hensel field of residue characteristic $0$ can be viewed in this way. See Example 12.8.

By a $++$ constructible subset of $F^a$, we mean a set of the form $X(F) = X \cap F^a$, $X$ a quantifier-free formula of $\mathbb{T}^+$. Let $VF^+(F)$ be the category of such sets, and $++$-constructible functions between them. The Grothendieck semiring $K_+VF^+(F)$ is thus the quotient of $K_+VF$ by the semiring congruence

\[I_F = \{([X],[Y]) : X,Y \in \text{Ob } VF^+, X(F) = Y(F)\}\]

(one can verify this is an ideal; in fact if $X(F) = Y(F)$ and $X \simeq X'$, then there exists $Y' \simeq Y$ with $X'(F) = Y'(F)$.)

Similarly we can define $I^{RV}_F$ and form $K_+RV(F) \simeq (K_+RV)/I^{RV}_F$. As usual, let $I_{sp}$ denote the congruence generated by $([1],[R^{>0}]), ([1],[1])$, and $I^{RV}_F + I_{sp}$ their sum.

Claim If $([X],[X']) \in I_F$ then $(\mathfrak{f}[X], \mathfrak{f}[X']) \in I^{RV}_F + I_{sp}$.

Proof. We may assume, changing $X$ within the $VF$-isomorphism class $[X]$, that $X(F) = X'(F)$. Then $X(F) = (X \cup X')(F) = X'(F)$, and it suffices to show: $(\mathfrak{f}[X], \mathfrak{f}[X \cup X'], \mathfrak{f}[X'], \mathfrak{f}[X \cup X']) \in I^{RV}_F$. Thus we may assume $X \subseteq X'$. Let $Z = X' \setminus X$. Then $Z(F) = \emptyset$, and it suffices to show: $(\mathfrak{f}(Z), \emptyset) \in I^{RV}_F$. Now $\mathfrak{f}(Z) = [Y]$ for some $Y$ with $Z$ definably isomorphic to $LY$. So $LY(F) = \emptyset$, hence $Y(F) = \emptyset$. Thus $(Y, \emptyset) \in I^{RV}_F$, as required. \hfill \Box

As an immediate consequence we have:

**Proposition 12.6.** Assume $F \leq M \models \mathbb{T}$, with $F$ closed under definable functions of $\mathbb{T}$. The homomorphism $\mathfrak{f}$ of Theorem 8.8 induces a homomorphism

\[\mathfrak{f}_F : K_+VF^+(F) \to K_+RV^+(F)/I_{sp}\]

\hfill \Box

12.4. Quantifier elimination for Hensel fields. Let $\mathbb{T}$ be a $\mathbb{V}$-minimal theory in a language $L_{\mathbb{T}}$, with sorts $(VF, RV)$ (cf. §2.1.) Assume $\mathbb{T}$ admits quantifier-elimination, and moreover that any definable function is given by a basic function symbol. This can be achieved by an expansion-by-definition of the language.

Let $\mathbb{T}_h = (\mathbb{T})_v \cup \{(\forall v \in RV)(\exists x \in VF) (rv(x) = y)\}$.

A model of $\mathbb{T}_h$ is thus the same as a substructure $A$ of a model of $\mathbb{T}$, such that $RV(A) = rv(VF(A))$. 

Lemma 12.7. Any formula of $L_T$ is $T$-equivalent to a Boolean combination of formulas in VF-variables alone, and formula $\psi(t(x),u)$ where $t$ is a sequence of terms for functions $VF^n \rightarrow RV$, $u$ is a sequence of RV-variables, and $\psi$ is a formula of RV variables only.

Proof. This follows from stable embeddedness of RV, Corollary 3.24, Lemma 2.8 and the fact (Lemma 7.10) that definable functions into $\Gamma$ factor through definable functions into RV. □

Example 12.8. If $T = ACVF(0,0)$, then $T_h$ is an expansion-by-definition of the theory of Hensel fields of residue characteristic zero.

Proof. We must show that a Henselian valued field is definably closed in its algebraic closure, in the two sorts VF, RV.

Let $K \models T_{Hensel}$, $K \subseteq M \models ACVF$. Let $X \subseteq VF^k \times RV^l$, $Y \subseteq VF^{k'} \times RV^{l'}$ be ACVF$_K$-definable sets, and $F : X \rightarrow Y$ an ACVF$_K$-definable bijection. We have to show that $F(X \cap K^k \times RV(K)^l) = Y \cap K^{k'} \times RV(K)^{l'}$.

$K^{alg}$ is an elementary submodel of $M$; we may assume $K^{alg} = M$. By one of the characterizations of Henselianity, the valuation on $K$ extends uniquely to $K^{alg}$. Hence every field automorphism of $M$ over $K$ is a valued field automorphism. So $K$ is the fixed field of $Aut(M/K)$ (in the sense of valued fields), and hence $K = \text{cl}(K)$. Since ACVF$_K$ is effective, any definable point of RV lifts to a definable point of VF; so $\text{cl}(K) \cap RV = RV_K$. Thus $K$ is definably closed in $M$ in both sorts. □

Let $L \supset L_T$; assume $L \setminus L_T$ consists of relations and functions on RV only. If $A \subseteq M \models T$, let $L_T(A)$ be the languages enriched with constants for each element of $A$; let $T_h(A) = T_A \cup T_h$, where $T_A$ is the set of quantifier-free valued field formulas true of $A$.

Proposition 12.9. $T_h$ admits elimination of field quantifiers.

Proof. Let $A$ be as above. Let $\Phi_A$ be the set of $L(A)$-formulas with no VF-quantifiers.

Claim. Let $\phi(x,y) \in \Phi_A$ with $x$ a free VF-variable. Then $(\exists x)\phi(x,y)$ is $T_h(A)$-equivalent to a formula in $\Phi_A$.

Proof. By the usual methods of compactness and absorbing the $y$-variables into $A$, it suffices to prove this when $x$ is the only variable. Assume first that $\phi(x)$ is an $L_T(A)$-formula. By Lemma 4.2, there exists an ACVF-definable bijection between the definable set defined by $\phi(x)$, and a definable set of the form $L^\emptyset(x',u)$, where $\emptyset$ is an $L_T(A)$-formula in RV-variables only (including a distinguished variable $x'$ on which $L$ acts.) By definition of $T_h$, in any model of $T_h$, $\phi$ has a solution iff $L^\emptyset(x',u)$ has a solution. But clearly $L^\emptyset(x',u)$ has a solution iff $\emptyset(x',u)$ does. Thus $T_h(A) \models (\exists x)\phi(x) \iff (\exists x',u)\emptyset(x',u)$.

Now let $\phi(x)$ be an arbitrary $\Phi_A$ formula. Let $\Psi$ be the set of formulas of $L(A)$ involving RV-variables only. Let $\Theta$ be the set of conjunctions of formulas of $L_T(A)$ in VF-variables only, and of formulas of the form $\psi(t(x))$, where $\psi \in \Psi$ and $t$ is a term of $L_T(A)$.
The set of disjunctions of formulas in $\Theta$ is then closed under Boolean combinations, and under existential RV-quantification. By Lemma 12.7 it includes all $L_T$-formulas, up to equivalence; and also all formulas in RV-variables only. Thus $\phi(x)$ is a disjunction of formulas in $\Theta$, and we may assume $\phi(x) \in \Theta$. Say $\phi = \phi_0(x) \land \psi(t(x))$, with $\phi_0 \in L_T(A)$ and $\psi \in \Psi$. By Claim 1, for some formula $\rho(y)$ of $\Phi_A$, we have $T_h(A) \models \rho(y) \iff (\exists x)(t(x) = y \land \phi_0(x))$. Hence $(\exists x)\phi(x) \iff (\exists y)(\psi(y) \land \rho(y))$. □

Quantifier elimination now follows by induction. □

Remark Since only field quantifiers are mentioned, this immediately extends to expansions in the field sort.
In particular, one can split the sequence 0 \rightarrow k^* \rightarrow RV \rightarrow \Gamma \rightarrow 0 if one wishes. This yields the quantifier-elimination [29] in the Denef-Pas language.

The results of Ax-Kochen and Ershov, and the large literature that developed around them, appeared to require methods of “quasi-convergent sequences”. It is thus curious that they can also be obtained directly from Robinson’s earlier and purely “algebraic” quantifier elimination for ACVF. Note that in the case of ACVF, there is no need to expand the language to obtain QE; and then Lemma 12.7 requires no proof beyond inspection of the language.

12.5. **Rational points: definable sets and morphisms.** In this subsection we will work with completions \( T \) of \( T_H \cup \{(\exists \varepsilon \in \Gamma)(\varepsilon > 0)\} \). These are theories of valued fields of residue characteristic 0, possibly expanded, not necessarily algebraically closed. The language of \( T \) is thus the language of \( T^+ \). The words formula, type, definable closure will refer to quantifier-free formulas of \( T^+ \). Definable closure, types with respect to \( T \) are referred to explicitly as \( \text{dcl}^T \), \( \text{tp}^T \) etc.

Let \( F \models T \). Since \( F \models T_V \), \( F \) embeds into a model \( M' \) of \( T^+ \). Since \( \Gamma(F) \not\equiv (0) \), by Proposition 3.51 and Lemma 3.49, there exists \( F' \subseteq M' \) containing \( F \), with \( \Gamma(F') = \Gamma(F) \), and \( M = \text{acl}(F') \) an elementary submodel of \( M' \). Hence \( F \) embeds into a model \( M \) of \( T^+ \) with \( \Gamma(F) \) cofinal in \( \Gamma(M) \).

**Lemma 12.10.** Let \( F \models T \), \( F \leq M \models T^+ \), \( \Gamma(F) \) cofinal in \( \Gamma(M) \). Let \( A \) be a substructure of \( M \), \( c \in F \), \( B = A(c) \cap RV \cap F \),

1. \( \text{tp}(c/B) \cup T_B \) implies \( \text{tp}^T(c/B) \).
2. Assume \( c \) is \( T_A \)-definable. Then \( c \in \text{dcl}(A,b) \) for some \( b \in B \).

**Proof.** (1) This follows immediately from the quantifier elimination for \( T \) and Lemma 12.1 (1).

(2) We have \( B \subseteq \text{dcl}^T(A) \cap RV \). We must show that \( c \in \text{dcl}(A \cup B) \). Let \( p = \text{tp}(c/A \cup B) \).

By (1), \( p \) generates a complete type of \( T_{A,B} \). Since this is the type of \( c \) and \( c \) is \( T_A \)-definable, some formula \( P \) in the language of \( T_{A,B} \) with \( P \in p \) has a unique solution in \( F \). Now the values of \( F \) are cofinal in the value group of \( F^0 \); so \( P \) cannot contain any ball around \( c \) (any such ball would have an additional point of \( F \), obtained by adding to \( c \) some element of large valuation.) Let \( P' \) be the set of isolated elements of \( P \); then \( P' \) is finite (as is the case for every definable \( P \), \( T_A \)-definable, and \( c \in P' \). By Lemma 3.9, there exists an \( T_A \)-definable bijection \( f : P' \rightarrow Q \) with \( Q \subseteq RV^n \). Then \( f(c) \in \text{dcl}_F(A) = B \), and \( c = f^{-1}(f(c)) \in \text{dcl}(A \cup B) \).

**Corollary 12.11.** Two definably isomorphic definable subsets of \( F \) have the same class in \( K_1 VF^+(F) \).

**Proof.** \( T \)-definable bijections are restrictions of \( T^+ \)-definable bijections. Hence Corollary 12.2 is true with \( T \) replacing \( T^+ \).

Thus Proposition 12.6 includes a change-of-variable formalism for definable bijections.

12.6. **Some specializations.**

12.6.1. **Tim Mellor’s Euler characteristic.** Consider the theory RCVF of real closed valued fields. Let \( RV_{RCVF} \), \( RES_{RCVF} \), \( VAL_{RCVF} \) denote the categories of definable sets and maps that lift to bijections of RCVF (on RV and on the residue field, value group respectively. We do not need to use the sorts of RES other than the residue field here, say all structures \( A \) of interest have \( \Gamma_A \) divisible.) From Proposition 12.6 and Corollary 12.11 we obtain an isomorphism: \( K(\text{RCVF}) \rightarrow K(\text{RV}_{RCVF})/([0]_1 - [\text{RV}^>0]_1 - [0]_0) \).
The residue field is a model of the theory RCF of real closed fields; $\mathbb{K}(RCF) = \mathbb{Z}$ via the Euler characteristic (cf. [36]). Since the ambient dimension grading is respected here, $\mathbb{K}(\text{RES}_{RCF}) = \mathbb{Z}[t]$.

The value group is a model of DOAG, and moreover, any definable bijection on $\Gamma[n]$ for fixed $n$ lifts to RV and indeed to RCFVF. This is because the multiplicative group of positive elements is uniquely divisible, and so $SL_n(\mathbb{Q})$ acts the $n$th power of this group. By Proposition 9.4, $\mathbb{K}(DOAG)[n] = \mathbb{Z}^2$ for each $n \geq 1$, and $K(\text{VAL}_{RCFVF}) = \mathbb{Z}[s][2] := \{(f, g) \in \mathbb{Z}[s] : f(0) = g(0)\}$. Thus $K(\text{RV}_{RCFVF} = \mathbb{Z}[t] \otimes \mathbb{Z}[s][2] \leq \mathbb{Z}[t, s]^2$; and $J$ is identified with the class $(1, 1) - (0, -s) - (t, t)$. Thus we obtain two homomorphisms $K(\text{RV}_{RCFVF})/J \rightarrow \mathbb{Z}[s]$ (one mapping $t \mapsto 1$, the other with $t \mapsto 1 - s$; and as a pair they are injective.

Equivalently, we have found two ring homomorphisms $\chi, \chi' : K(RCFVF) \rightarrow \mathbb{Z}[t]$. One of these was found in [27].

12.6.2. Cluckers-Haskell. Take the theory of the $p$-adics. By Proposition 12.6 and Corollary 12.11 we obtain an isomorphism: $K(pCF) \rightarrow K(\text{RV}_{pCF})/I_{sp}$. However $\text{RV}_{pCF}$ is a finite extension of $\mathbb{Z}$, and evidently $K(\mathbb{Z}) = 0$, since $[[0, \infty]] = [[1, \infty]]$. Thus $K(pCF) = 0$.

12.7. Higher dimensional local fields. We have seen that the Grothendieck group of definable sets with volume forms loses a great deal of information compared to the semi-group. Over fields with discrete value groups, restricting to bounded sets is helpful; in this the Grothendieck group retains information about volumes. In case of higher dimensional local fields, with value group is $A = \mathbb{Z}^n$, simple boundedness is insufficient to save from collapse. We show that using a simple-minded notion of boundedness is only partly helpful, and loses much of the volume information (all but one $\mathbb{Z}$ factor.)

**Example 12.12.** Let $K_{p}^{\text{bdd}}(\text{Th}(\mathbb{C}(s_1))((s_2)))[n])$ be the Grothendieck ring of definable bounded sets and measure preserving maps in $\mathbb{C}(s_1))((s_2))$ (with $\text{val}(s_1) < \text{val}(s_2)$). Let $Q^1$ denote the class of the thin annulus of radius $t$. In particular $Q^0$ is the volume of the units of the valuation ring. Then in $K_{p}^{\text{bdd}}(\text{Th}(\mathbb{C}(s_1))((s_2)))[2])$ we have for example $(Q^0)^2 = 0$. To see this directly let

$$Y = \{(x, y) : \text{val}(x) = 0, \text{val}(y) = 0\}, \ X = \{(x, y) : 0 < 2\text{val}(x) < \text{val}(s_2), \text{val}(x) + \text{val}(y) = 0\}$$

Then $X$ is bounded. Let $f(x, y) = (x/s_1, s_1y)$. Then $f$ is a measure preserving bijection $X \rightarrow X' = \{(x, y) : 0 < 2(\text{val}(x) + \text{val}(s_1)) < \text{val}(s_2), \text{val}(x) + \text{val}(y) = 0\}$ . But in $\mathbb{C}(s_1))((s_2))$, $2\text{val}(x) < \text{val}(s_2)$ iff $2(\text{val}(x) + \text{val}(s_1)) < \text{val}(s_2)$ so $X'((\mathbb{C}(s_1))((s_2))) = X((\mathbb{C}(s_1))((s_2)) \cup Y((\mathbb{C}(s_1))((s_2)))$.

**Remark 12.13.**

$(2[[0, y/2]] - [[0, y]])/2(2[[0, y/2]] - [[0, y]]))$, is a class of the Grothendieck group of $\Gamma$ that vanishes identically in the $\mathbb{Z}$-evaluation, but not in the $\mathbb{Z}^2$-evaluation.

13. The Grothendieck group of algebraic varieties

Let $X, Y$ be smooth nonsingular curves in $\mathbb{P}^3$, or in some other smooth projective variety $Z$, and assume $Z \setminus X, Z \setminus Y$ are birationally isomorphic. Say $X, Y, Z$ are defined over $\mathbb{Q}$. Then for almost all $p$, $|X(F_p)| = |Y(F_p)|$, as one may see by counting points of $Z, Z \setminus X$ and subtracting. It follows from Weil’s Riemann hypothesis for curves that $X, Y$ have the same genus, from Faltings that $X, Y$ are isomorphic if the genus is 2 or more, and from Tate that $X, Y$ are isogenous if the genus is one. It was this observation that led Kontsevich and Gromov to ask if $X, Y$ must actually be isomorphic. We show that this is the case below.

\[\text{[This already follows from [22], who use different methods.]}\]
Theorem 13.1. Let $X, Y$ be two smooth $d$-dimensional subvarieties of a smooth projective $n$-dimensional variety $V$, and assume $V \setminus X, V \setminus Y$ are biregularly isomorphic. Then $X, Y$ are stably birational, i.e., $X \times \mathbb{A}^{n-d}, Y \times \mathbb{A}^{n-d}$ are birationally equivalent. If $X, Y$ contain no rational curves, then $X, Y$ are birationally equivalent.

While we do not obtain a complete characterization in dimensions $> 1$, the results and method of proof do show that the answer lies in synthetic geometry and is not cohomological in nature.

Let $\text{Var}_{K^2}$ be the category of algebraic varieties over a field $K$ of characteristic 0. Let $[X]$ denote the class of a variety $X$ in the Grothendieck semigroup $K^+_+(\text{Var}_{K^2})$. We allow varieties to be disconnected. As all varieties will be over the same field $K$, we will write $\text{Var}$ for $\text{Var}_{K^2}$. Let $K^+\text{Var}_n$ be the Grothendieck semigroup of varieties of dimension $\leq n$.

For the proof, we view $K$ as a trivially valued subfield of a model of $\text{ACVF}(0,0)$. We work with the theory $\text{ACVF}_K$, so that “definable” means $K$-definable with quantifier-free $\text{ACVF}$-formulas.

Note that $\text{RES} = k^*$ in $\text{ACVF}_K$; the only definable point of $\Gamma$ is 0, so the only definable coset of $k^*$ is $k^*$ itself.

The residue map is an isomorphism on $K$ onto a subfield $K_{\text{RES}}$ of the residue field $k$. In particular, any smooth variety $V$ over $K$ lifts canonically to a smooth scheme $V_0 = V \otimes_K 0$ over 0, with generic fiber $V_{VF} = V_0 \otimes_0 VF$ and special fiber $V_0 \otimes_0 k = V \otimes_k k$. We have a reduction homomorphism $\rho_V : V(0) \to V(k)$. We will write $V(0), V(VF)$ for $V_0(0), V_0(VF)$.

Given $k \leq n$ and a definable subset $X$ of $RV^*$ of dimension $\leq k$, let $[X]_k$ be the class of $X$ in $K_+RV[k] \subseteq K_+RV[\leq n]$. Thus if $\dim(X) = d$ we have $n - d + 1$ classes $[X]_k$, $d \leq k \leq n$, in different direct factors of $K_+RV[\leq n]$. We also use $[X]_k$ to denote the image of this class in $K_+RV[\leq n]/I_{sp}$. This abuse of notation is not excessive since for $n \leq N$, $K_+RV[\leq n]/I_{sp}$ embeds in $K_+RV[\leq N]/I_{sp}$ (Lemma 8.7).

Let $SD_d$ be the image of $K_+RV[\leq d]$ in $K_+RV[\leq N]/I_{sp}$. Let $WD^n_d$ be the subsemigroup of $RV[n]$ generated by $\{[X] : \dim(X) \leq d\}$, and use the same letter to denote the image in $RV[\leq N]/I_{sp}$. Let $FD^n = SD^n_{n-1} + WD^n_{n-1}$. We write $a \sim b$ ($FD^n$) for $(3u, v \in FD^n)(a + u = b + v)$. More generally, for any subsemigroup $S'$ of a semigroup $S$, write $a \sim b(S')$ for $(3u, v \in S')(a + u = b + v)$.

We write $K(RV[\leq n])/I_{sp}$ for the groupification of $K_+(RV[\leq n])/I_{sp}$.

Lemma 13.2. Let $V$ be a smooth projective $k$-variety of dimension $n$, $X$ a definable subset of $V(k)$. Then

$$\text{d}(\rho_V^{-1}(X)) = [X]_n$$

Proof. Let $X = (X,f)$ where $f : X \to RV^n$ is a finite-to-one map. We have to show that $[LX] = [\rho_V^{-1}(X)]$ in $K_+(VF[n])$, i.e., that $LX, \rho_V^{-1}(X)$ are definably isomorphic. By Lemma 2.3 this reduces to the case that $X$ is a point $p$. Find an open affine neighborhood $U$ of $V$ such that $\rho_V^{-1}(p) \subseteq U(0)$, and $U$ admits an étale map $g : V \to \mathbb{A}^n$ over $k$. Now $U(0) \simeq \mathbb{A}^n \times_{\text{res}, k} U(k)$. This reduces the lemma to the case of affine space, where it follows from the definition of $L$. $\square$

Lemma 13.3. Let $X$ be a $a K$-variety of dimension $\leq d$.

1. $\text{d}(X(VF)) \in SD_d = K_+(RV[\leq d])/I_{sp}$
2. If $X$ is a smooth complete variety of dimension $d$ then $\text{d}(X(VF)) = [X]_d$.
3. If $X$ is a variety of dimension $d$ then $\text{d}(X(VF)) \sim [X]_d(FD^d)$.

Proof. (1) is obvious, since $\dim(X(VF)) \leq d$. 

(2) By Grothendieck’s valuative criterion for properness, $X(\mathbb{V}_F) = X(\mathbb{O})$. We thus have a map $\rho_F : X(\mathbb{V}_F) = X(\mathbb{O}) \to X(\mathbb{K})$. For $\alpha \in X(\mathbb{K})$, let $X_\alpha(\mathbb{V}_F) = \rho_F^{-1}(\alpha)$.

Since $X$ is smooth of dimension $d$ it is covered by Zariski open neighborhoods $U$ admitting an étale map $f_U : U \to \mathbb{A}^d$, defined over $\mathbb{K}$; let $\mathcal{S}$ be a finite family of such pairs $(U, f_U)$, with $\bigcup_{(U, f_U) \in \mathcal{S}} U = X$. We may choose a definable finite-to-one $f : X \to \mathbb{A}^d$, defined over $\mathbb{K}$, such that for any $x \in X$, for some pair $(U, f_U) \in \mathcal{S}, f(x) = f_U(x)$. We have $L([X]_d) = L(X, f) = \mathbb{V}_F^d \times_{r_F, f} X(\mathbb{K})$. We have to show that $L(X, f)$ is definably isomorphic to $X(\mathbb{V}_F)$.

By Lemma 2.3 it suffices to show that for each $\alpha \in X(\mathbb{K})$, $\mathbb{V}_F^d \times_{r_F, f} \{\alpha\}$ is $\alpha$-definably isomorphic to $X_\alpha(\mathbb{V}_F)$. Now $\mathbb{V}_F^d \times_{r_F, f} \{\alpha\} = r_F^{-1}(f(\alpha))$. We have $f(\alpha) = f_U(\alpha)$ for some $(U, f_U) \in \mathcal{S}$ with $\alpha \in U$. Since $f_U$ is étale, it induces a bijective map $U_\alpha(\mathbb{V}_F) \to r_F^{-1}(f(\alpha))$. But $X_\alpha(\mathbb{V}_F) = U_\alpha(\mathbb{V}_F)$, so the required isomorphism is proved.

(3) If $X, Y$ are birationally equivalent, then $[X]_d \sim [Y]_d (WD_d', w_d')$, while $X(\mathbb{V}_F), Y(\mathbb{V}_F)$ differ by $\mathbb{V}_F$-definable sets of dimension $< d$, so $\rho_F(X(\mathbb{V}_F)) \sim \rho_F((Y(\mathbb{V}_F))(SD_d'))$. Using the resolution of singularities in the form: every variety is birationally equivalent to a smooth nonsingular one, we are done by (2). With a more complicated induction we should be able to dispense with this use of Hironaka’s theorem. □

Lemma 13.4. Let $V$ be a smooth projective $K$-variety, $X, Y$ closed subvarieties. Let $F : V \setminus X \to V \setminus Y$ a birational isomorphism. Let $V_0, V_{VF}, V_K, F_{VF}$, etc. be the objects obtained by base change. Then $F_{VF}$ induces a bijection $V(\mathbb{V}_F) \setminus X(\mathbb{V}_F) \to V(\mathbb{V}_F) \setminus Y(\mathbb{V}_F)$, and

$$F_{VF}(\rho_F^{-1}(X) \setminus X(\mathbb{V}_F)) = \rho_F^{-1}(Y) \setminus Y(\mathbb{V}_F)$$

Proof. The first statement follows from the Lefschetz principle since $VF$ is algebraically closed.

Since $V$ is projective, $V(\mathbb{V}_F) = V(\mathbb{O})$, and one can define for $v \in V$ the valuative distance $d(v, X)$, namely the greatest $\alpha \in \Gamma$ such that the image of $x$ in $V(\mathbb{O}/\alpha)$ lies in $X(\mathbb{O}/\alpha)$.

Let $\mathcal{F}$ be the Zariski closure in $V^2$ of the graph of $F$. Then $\mathcal{F} \cap (V \setminus X) \times (V \setminus Y)$ is the graph of $F$. In fact, in any algebraically closed field $L$, we have

$$\text{(29)} \quad \text{if } a \in V(L) \setminus X(L) \text{ and } (a, b) \in \mathcal{F}(L) \text{ then } b \in V(L) \setminus Y(L)$$

and conversely.

Suppose for the sake of contradiction that in some $M \models ACVF_K$ there exist $a \in \rho_F^{-1}(X), b \notin \rho_F^{-1}(Y), (a, b) \in \mathcal{F}$. So $d(a, X) = \alpha > 0, d(b, Y) = 0$. Let

$$C = \{\gamma \in \Gamma : (\forall n \in \mathbb{N}) n\gamma < \alpha\}$$

We may assume by compactness that $C(M) \neq \emptyset$. Let

$$I = \{y \in \mathbb{O}(M) : \text{val}(y) \notin C\}$$

so that $I$ is a prime ideal of $\mathbb{O}(M)$.

Let $L$ be the field of fractions of $\mathbb{O}(M)/I$. Let $\overline{a}, \overline{b}$ be the images of $a, b$ in $L$. Then $(\overline{a}, \overline{b}) \in \mathcal{F}$, and $\overline{a} \in X, \overline{b} \notin Y$; contradicting (29) □

Proof of Theorem 13.1. By Lemma 13.4, there exists a definable bijection $\rho_F^{-1}(X) \setminus \rho_F^{-1}(Y) \setminus Y$. Applying $\rho_F : K(\mathbb{V}_F[n]) \to K(\mathbb{R}[\leq n])/I_{sp}$, and using Lemmas 13.2 and 13.3, we have $[X]_n - [X]_d = [Y]_n - [Y]_d$. Applying the first retraction $K(\mathbb{R}[\leq n])/I_{sp} \to K(\text{RES}[n])$ of Theorem 10.5, we obtain

$$[X]_n - [X \times \mathbb{A}^{n-d}]_n = [Y]_n - [Y \times \mathbb{A}^{n-d}]_n$$

in $K(\text{RES}[n]) = K(\text{Var}_n)$. So

$$[X \times \mathbb{A}^{n-d} \cup Y]_n + [Z] = [Y \times \mathbb{A}^{n-d} \cup X]_n + [Z]$$
for some $Z$ with $\dim(Z) \leq n$, where now the equality is of classes in $K_0\text{Var}_n$. Counting birational equivalence classes of varieties of dimension $n$, we see that $X \times \mathbb{A}^{n-d}, Y \times \mathbb{A}^{n-d}$ must be birationally equivalent. The last sentence follows from the lemma below. 

Lemma 13.5. Let $X, Y$ be varieties containing no rational curve. Let $U$ be a variety such that there exists a surjective morphism $\mathbb{A}^m \to U$. If $X \times U, Y \times U$ are birationally equivalent, then so are $X, Y$.

Proof. For any variety $W$, let $\mathcal{F}(W)$ be the set of all rational maps $g : \mathbb{A}^1 \to W$. Write $\text{dom}(g)$ for the maximal subset of $\mathbb{A}^1$ where $g$ is regular; so $\text{dom}(g)$ is cofinite in $\mathbb{A}^1$. Let $R_W = \{(g(t), g(t')) \in W^2 : g \in \mathcal{F}(W), t, t' \in \text{dom}(g)\}$. Let $E_W$ be the equivalence relation generated by $R_W$, on points in the algebraic closure. $R_W, E_W$ may not be constructible in general, but in the case we are concerned with they are:

Claim Let $W \subseteq X \times U$ be a Zariski dense open set. Let $\pi : W \to X$ be the projection. Then $\pi(w) = \pi(w')$ iff $(w, w') \in E_W$.

Proof. If $g \in \mathcal{F}(U)$, then $\pi \circ g : \text{dom}(g) \to X$ is a regular map; hence by assumption on $X$ it is constant. It follows that if $(w, w') \in R_W$ then $\pi(w) = \pi(w')$, and hence if $(w, w') \in E_W$ then $\pi(w) = \pi(w')$. Conversely, assume $u', u'' \in U$ and $\pi(u') = \pi(u'')$; then $u' = (x, u')$, $u'' = (x, u'')$ for some $x \in X$. The line through $v, v''$ intersects $h^{-1}(U_x)$ in a nonempty open set. This gives a regular map $f$ from the affine lines, minus finitely many points, into $U$, passing through $u', u''$. So $t \mapsto (x, f(t))$ gives a rational map from $\mathbb{A}^1$ to $W$, passing through $(u', u'')$; and so $(u', u'') \in R_W$ and certainly in $E_U$. 

Using the Claim, we prove the lemma. Let $W_X \subseteq X \times U$, $W_Y \subseteq Y \times U$ be Zariski dense open, and $F : W_X \to W_Y$ a birational isomorphism. Then $F$ takes $E_{W_X}$ to $E_{W_Y}$. Moving now to the category of constructible sets and maps, quotients by constructible equivalence relations exist, and $W_X / E_{W_X}$ is isomorphic as a constructible set to $W_Y / E_{W_Y}$. Let $\pi_X : W_X \to X, \pi_Y : W_Y \to Y$ be the projections. By the Claim, $W_X / E_{W_X} = \pi_X(W_X) = X'$. Similarly $W_Y / E_{W_Y} = \pi_Y(W_Y) = Y'$. Now since $W_X, W_Y$ are Zariski dense, so are $X', Y'$. Thus $X, Y$ contain isomorphic Zariski dense constructible sets, so they are birationally equivalent. 

Remark The condition on $X, Y$ may be weakened to the statement that they contain no rational curve through a generic point; i.e. that there exist proper subvarieties $(X_i : i \in I)$ defined over $K$, such that for any field $L \subset K$, any rational curve on $X \times_K L$ is contained in some $X_i \times_K L$.
