A FAST DIRECT SOLVER FOR THE BIHARMONIC PROBLEM IN A RECTANGULAR GRID*

MATANIA BEN-ARTZI[†], JEAN-PIERRE CROISILLE[‡], AND DALIA FISHELOV[§]

Abstract. We present a fast direct solver methodology for the Dirichlet biharmonic problem in a rectangle. The solver is applicable in the case of the second order Stephenson scheme [J. W. Stephenson, *J. Comput. Phys.*, 55 (1984), pp. 65–80] as well as in the case of a new fourth order scheme, which is discussed in this paper and is based on the capacitance matrix method ([B. L. Buzbee and F. W. Dorr, *SIAM J. Numer. Anal.*, 11 (1974), pp. 1136–1150], [P. Bjørstad, *SIAM J. Numer. Anal.*, 20 (1983), pp. 59–71]). The discrete biharmonic operator is decomposed into two components. The first is a diagonal operator in the eigenfunction basis of the Laplacian, to which the FFT algorithm is applied. The second is a low-rank perturbation operator (given by the capacitance matrix), which is due to the deviation of the discrete operators from diagonal form. The Sherman–Morrison formula [G. H. Golub and C. F. Van Loan, *Matrix Computations*, 3rd ed., John Hopkins University Press, Baltimore, MD, 1996] is applied to obtain a fast solution of the resulting linear system of equations.

1. Introduction. The accurate resolution of linear fourth order elliptic problems, such as the biharmonic equation, is of great importance in many fields of applied mathematics. Specific examples are the computation of the streamfunction in incompressible fluid dynamics or in problems in elasticity theory. From the numerical point of view, two essential issues are the accuracy of the scheme and the availability of a fast solver.

Finite-difference schemes for the biharmonic problem on rectangles fall broadly into two categories: coupled and noncoupled schemes. In coupled schemes, the problem is decomposed into two Poisson problems, combined with boundary conditions; classical works include [31], [32], [14], [27]. When one applies such a scheme to the Dirichlet biharmonic problem, one encounters difficulties in the design of artificial boundary conditions for the first Poisson problem, whereas the second one is overdetermined. In the fluid dynamics context, this question is related to the design of an artificial boundary condition for the vorticity of the flow.

Here we focus on a noncoupled scheme, namely the nine-point (second order) Stephenson scheme introduced in [33]. This scheme has been successfully applied to the numerical simulation of the time-dependent Navier–Stokes system (see [17], [4], [3]). Its main advantage, in contrast with the usual thirteen-point scheme (see, e.g.,

[24, 12, 10, 8]), is that it allows the construction of a time-dependent solver, which is closely related to the partial differential problem. A crucial feature of the scheme is the absence of artificial boundary conditions on the vorticity. This permits the construction of a compact scheme, which handles near boundary points in the same manner as internal points (see also [20], [19]). The solution of the linear system of discretized equations requires a fast solver.

The main goal of this paper is to present a fast solver for compact discretizations of the biharmonic problem. This is done by the *capacitance matrix* formulation. In the first part of this paper we construct the capacitance matrix formulation for the Stephenson scheme on a rectangular grid. We show how it is efficiently applied to the solution of the discrete biharmonic problem.

In the second part of this paper, a fourth order accurate extension of the Stephenson scheme is introduced. The new fourth order discrete biharmonic equation is solved using a modified version of the second order algorithm. The key feature of the scheme consists of simple representation of the capacitance matrix in the eigenfunction basis of the Laplacian. It enables us to efficiently compute the capacitance matrix and to solve the resulting low-rank linear system using a diagonal preconditioned conjugate-gradient method. In addition, the gradient and the Laplacian of the solution of the biharmonic problem are obtained as byproducts of the solver.

To put this paper in the context of existing literature, we make the following remarks.

- A fourth order version of the Stephenson scheme was introduced in [33]. A multigrid solver for this scheme is devised in [1]. In the context of the equation $\Delta^2\psi = f$, it uses the values of f at five points (in the nine-point stencil). In contrast, our scheme uses only the value of f at the center point. When f itself is a function of ψ (e.g., $\Delta\psi$), this leads to a significant simplification of the algorithm.

- A scheme based on orthogonal spline collocation (OSC) has been investigated in [34], [25], [5]. This scheme is fourth order accurate and the linear system is solvable at a cost of $O(N^2 \operatorname{Log}(N))$ operations, where N is the number of grid points in one direction. An almost block diagonal solver, [16], [2], is used as a basis of the fast solver in [5].

- The algorithm presented here runs parallel the lines of the capacitance matrix principle of Golub (appendix of [15]), Buzbee and Dorr [10] (thirteen-point scheme, $O(N^3)$ solver), Bjørstad [8] (thirteen-point scheme, $O(N^2)$ solver), Bjørstad and Tjøstheim [9], and Shen's Legendre or Hermite Galerkin schemes of Shen [29], [30], $O(N^3)$ solver. It consists basically of a decomposition of the matrix, which represents the scheme, into a sum of a diagonal operator in the eigenfunction basis of the (five-point) Laplacian, and of a low-rank perturbation, called the *capacitance matrix* [11]. Our algorithm is based on two ingredients: (i) application of the Sherman–Morrison formula with a low-rank capacitance matrix, (ii) resolution of the diagonal component in the inversion formula by the FFT method (see [7] for a similar application). We emphasize the fact that our algorithm is a direct (whereas in [21], [22] it is an iterative) solver.

The outline of this paper is as follows. In section 2 we recall the second order Stephenson scheme, using the notation introduced in [4], [3]. In section 3, we develop our fast solver for the biharmonic problem, including detailed algebraic derivation for the nine-point second order Stephenson operator. Section 4 is devoted to the

new fourth order scheme, for which a similar fast algorithm is developed. Finally, in section 5, we represent numerical results for both the second order and the fourth order schemes. The problems dealt with are mixed biharmonic-Laplacian problems, subject to nonhomogeneous Dirichlet boundary conditions. Computing efficiency is reported for several fourth order problems. The computational cost appears to be $O(N^2 \text{Log}(N))$, where N is the number of grid points in each direction. We note that a typical computing time of the solver for a 1024×1024 grid is ten seconds on a PC.

Finally, let us mention the work [28] for a comprehensive history of the biharmonic problem in two dimensions.

2. Notation.

2.1. Finite difference operators. We consider a square $\Omega = (0, L)^2$ with a uniform grid $x_i = ih$, $y_j = jh$, $i, j = 0, \ldots, N$, $h = 1/N$. The internal points are $x_i = ih$, $y_j = jh$, for $1 \leq i, j \leq N - 1$. Denote by $l_{h,0}^2$ the space of one-dimensional discrete functions (u_i) defined on $x_i = ih$, $1 \leq i \leq N - 1$. In two dimensions, $L_{h,0}^2$ is the space of discrete functions $(\psi_{i,j})$ defined on $x_i = ih$, $y_j = jh$, for $1 \leq i, j \leq N - 1$. The spaces $l_{h,0}^2$, $L_{h,0}^2$ are respectively equipped with the scalar products

$$(1) \qquad (u, v)_h = h \sum_{i=1}^{N-1} u_i v_i \ \forall u, v \in l_{h,0}^2; \quad (u, v)_h = h^2 \sum_{i,j=1}^{N-1} u_{i,j} v_{i,j} \ \forall u, v \in L_{h,0}^2.$$

For discrete function in $L_{h,0}^2$, we define the following centered operators:

$$(2) \qquad \begin{cases} \delta_x \psi_{i,j} = \dfrac{\psi_{i+1,j} - \psi_{i-1,j}}{2h}, & \delta_x^2 \psi_{i,j} = \dfrac{\psi_{i+1,j} + \psi_{i-1,j} - 2\psi_{i,j}}{h^2}, \\ \delta_y \psi_{i,j} = \dfrac{\psi_{i,j+1} - \psi_{i,j-1}}{2h}, & \delta_y^2 \psi_{i,j} = \dfrac{\psi_{i,j+1} + \psi_{i,j-1} - 2\psi_{i,j}}{h^2}, \end{cases}$$

and the mixed discrete derivative operator δ_{xy}

$$(3)$$
$$\delta_{xy} \psi_{i,j} = \delta_x \delta_y \psi_{i,j} = \dfrac{\psi_{i+1,j+1} - \psi_{i-1,j+1} - \psi_{i+1,j-1} + \psi_{i-1,j-1}}{4h^2}, \quad 1 \leq i, j \leq N - 1.$$

Consider the following fourth order partial differential problem in the square $\Omega = (0, L)^2$:

$$(4) \qquad \begin{cases} \left(-a\Delta + b\Delta^2\right)\psi(x, y) = f, & (x, y) \in \Omega, \\ \psi(x, y) = 0, \quad \dfrac{\partial \psi}{\partial n}(x, y) = 0, & (x, y) \in \partial\Omega, \end{cases}$$

where $a \geq 0$, $b > 0$ are two real constants. Problem (4) is approximated by the scheme

$$(5) \qquad \begin{cases} \left(-a\Delta_h + b\Delta_h^2\right)\psi_{i,j} = f_{i,j}, & \text{at interior points } (i, j), \\ \psi_{i,j} = 0, \quad \left(\dfrac{\partial \psi}{\partial n}\right)_{i,j} = 0, & \text{at boundary points } (i, j), \end{cases}$$

where
- $\Delta_h \psi_{i,j}$ is the five-point discrete Laplacian

$$(6) \qquad \Delta_h \psi_{i,j} = \delta_x^2 \psi_{i,j} + \delta_y^2 \psi_{i,j}, \quad 1 \leq i, j \leq N - 1,$$

- and Δ_h^2 is the nine-point discrete biharmonic (Stephenson approximation), defined by

$$(7) \qquad \Delta_h^2 \psi_{i,j} = \delta_x^4 \psi_{i,j} + \delta_y^4 \psi_{i,j} + 2\delta_x^2 \delta_y^2 \psi_{i,j}.$$

$\delta_x^2 \delta_y^2$ is the nine-point operator defined by $\delta_x^2 \delta_y^2 = \delta_x^2 \circ \delta_y^2$. The finite difference operators δ_x^4, δ_y^4 (introduced in [4], [3]) approximating $\frac{\partial^4}{\partial x^4}\psi$ and $\frac{\partial^4}{\partial y^4}\psi$ are the one-dimensional Stephenson operators

$$(8) \qquad \begin{cases} \delta_x^4 \psi = \dfrac{12}{h^2}\left(\delta_x \psi_x - \delta_x^2 \psi\right), \\ \delta_y^4 \psi = \dfrac{12}{h^2}\left(\delta_y \psi_y - \delta_y^2 \psi\right). \end{cases}$$

For any $\psi \in L_{h,0}^2$, the *Hermitian gradient* $(\psi_x, \psi_y) \in (L_{h,0}^2)^2$ in (8) is defined by the following relations between ψ and ψ_x and between ψ and ψ_y:

$$(9) \qquad \begin{cases} \left(I + \dfrac{h^2}{6}\delta_x^2\right)\psi_{x,i,j} = \delta_x \psi_{i,j}, \quad 1 \le i,j \le N-1, \\ \left(I + \dfrac{h^2}{6}\delta_y^2\right)\psi_{y,i,j} = \delta_y \psi_{i,j}, \quad 1 \le i,j \le N-1. \end{cases}$$

The latter form is for fourth order approximation for ψ_x for given values of ψ and fourth order approximations for ψ_y for given values of ψ. The two operators $\delta_x^4 \psi$, $\delta_y^4 \psi$ are fourth order approximations for $\frac{\partial^4}{\partial x^4}\psi$ and $\frac{\partial^4}{\partial y^4}\psi$ in the Fourier sense (see [3]). Then, the numerical scheme (5) may be written in the following way. Find $\psi_{i,j} \in L_{h,0}^2$ such that

$$(10) \qquad \left(-a\Delta_h + b\Delta_h^2\right)\psi_{i,j} = f_{i,j}.$$

The operator $-a\Delta_h + b\Delta_h^2$ is second order accurate because of the second order accuracy of the mixed term $\delta_x^2 \delta_y^2$ in (7) and of the five-point Laplacian (6). However, we will see in section 4 that the order of accuracy can be easily increased to fourth order by a slight modification of Δ_h^2 and Δ_h, keeping a pointwise source term $f_{i,j}$.

2.2. Matrix operators. We relate the bidimensional finite difference operators acting in $L_{h,0}^2$ with matrix operators of size $(N-1) \times (N-1)$ ($N \ge 2$), acting on a vector $u_{i,j} \in L_{h,0}^2$. Most of those operators are obtained as Kronecker products of $(N-1) \times (N-1)$ matrices.

We use the indexing of $u_{i,j} \in L_{h,0}^2$ as the column vector
$$(11)$$
$$U = \left[u_{1,1}, \ldots, u_{1,N-1}; u_{2,1}, \ldots, u_{2,N-1}; \ldots; u_{N-1,1}, \ldots, u_{N-1,N-1}\right]^T \in \mathbb{R}^{(N-1)^2}.$$

The bottom ordering of vector $U \in \mathbb{R}^{(N-1)^2}$ is obtained by letting the index j vary first. The notation "vect" stands indifferently for the operator which transforms any one-dimensional discrete function $u_i \in l_{h,0}^2$ to the vector $U = [u_1, \ldots, u_{N-1}]^T \in \mathbb{R}^{N-1}$ or any two-dimensional discrete function $u_{i,j} \in L_{h,0}^2$ to the vector U defined by (11) (see [36]).[1] Recall that the Kronecker product of the matrices $A \in \mathbb{M}_{m,n}$ and $B \in \mathbb{M}_{p,q}$

---

[1] Actually, in [36], the ordering of U is by lines.

is the matrix $A \otimes B \in \mathbb{M}_{mp,nq}$ defined by

$$(12) \qquad A \otimes B = \begin{bmatrix} a_{1,1}B & a_{1,2}B & \dots & a_{1,n}B \\ \dots & & & \\ \dots & & & \\ a_{m,1}B & a_{(N-1),2}B & \dots & a_{m,n}B \end{bmatrix}.$$

Let us define several $(N-1)\times(N-1)$ matrices that will be useful for the representation of our fast algorithm.

- *Centered one-dimensional Laplacian matrix*

  The symmetric positive definite matrix T is the standard tridiagonal matrix related to the three-point Laplacian

$$(13) \quad T_{i,m} = \begin{cases} 2, & m = i \\ -1, & |m - i| = 1, \\ 0, & |m - i| \geq 2 \end{cases} \qquad T = \begin{bmatrix} 2 & -1 & 0 & \dots & 0 \\ -1 & 2 & -1 & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & -1 & 2 & -1 \\ 0 & \dots & 0 & -1 & 2 \end{bmatrix}.$$

- The symmetric positive definite matrix P is deduced from T by ($I = I_{N-1}$ denotes the $(N-1) \times (N-1)$ identity matrix)

$$(14) \qquad P = 6I - T,$$

  or equivalently by

$$(15) \qquad P_{i,m} = \begin{cases} 4, & m = i \\ 1, & |m - i| = 1 \\ 0, & |m - i| \geq 2 \end{cases}, \qquad P = \begin{bmatrix} 4 & 1 & 0 & \dots & 0 \\ 1 & 4 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & 1 & 4 & 1 \\ 0 & \dots & 0 & 1 & 4 \end{bmatrix}.$$

  We also define $\bar{P} = I - \frac{1}{6}T$.

- The antisymmetric matrix $K = (K_{i,m})_{1 \leq i,m \leq N-1}$ is given by

  (16)

$$K_{i,m} = \begin{cases} \operatorname{sgn}(m - i), & |m - i| = 1 \\ 0, & |m - i| \neq 1 \end{cases}, \qquad K = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ -1 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & -1 & 0 & 1 \\ 0 & \dots & 0 & -1 & 0 \end{bmatrix}.$$

- For all $1 \leq i \leq N - 1$, $e_i \in \mathbb{R}^{N-1}$ is the column vector of the canonical basis of $\mathbb{R}^{N-1}$. The $(N-1) \times (N-1)$ matrix E_i is defined by

$$(17) \qquad E_i = e_i e_i^T, \quad 1 \leq i \leq N - 1.$$

  For all $u \in l_{h,0}^2$ and $U = \text{vect}(u) \in \mathbb{R}^{N-1}$,

$$(18) \qquad (E_i U)_j = \delta_{i,j} U_j, \quad 1 \leq i, j \leq N - 1$$

with $\delta_{i,j}$ the Kronecker symbol. If $U = \text{vect}(u), U_x = \text{vect}(u_x) \in \mathbb{R}^{N-1}$, then the following identities hold:

- *One-dimensional second order derivative δ_x^2*

$$(19) \qquad -\operatorname{vect}(\delta_x^2 u) = \frac{1}{h^2} TU.$$

- *One-dimensional centered gradient δ_x*

$$(20) \qquad \operatorname{vect}(\delta_x u) = \frac{1}{2h} KU.$$

- *One-dimensional Hermitian gradient u_x*

$$(21) \qquad \operatorname{vect}(u_x) = \frac{3}{h} P^{-1} KU.$$

- *One-dimensional Stephenson operator*

$$(22) \qquad \operatorname{vect}(\delta_x^4 u) = \frac{12}{h^2}\left[\frac{3}{2h^2} KP^{-1}K + \frac{1}{h^2}T\right]U = \frac{6}{h^4}\left[3KP^{-1}K + 2T\right]U.$$

Remark. The isomorphism operator "vect" which maps the discrete function $u \in L_{h,0}^2$ to the vector $U = \operatorname{vect}(u) \in \mathbb{R}^{(N-1)^2}$ induces a natural isomorphism of space operators. Let us denote by $\langle L, u \rangle$ the resulting discrete function obtained by the operation of an x linear operator L on a discrete function u. We associate to L an operator $\tilde{L}$, which acts on a vector U, such that

$$(23) \qquad \langle L, u \rangle = \langle \tilde{L}, U \rangle.$$

To simplify notation, from now on we identify the operators L and $\tilde{L}$ in cases where this notation does not lead to any confusion. For example (19) will be written

$$(24) \qquad -\delta_x^2 = \frac{1}{h^2} T.$$

Now we apply the same identification between operators in the bidimensional framework. We identify the discrete functions $u \in L_{h,0}^2$ and the vector $U \in \mathbb{R}^{(N-1)^2}$. The following bidimensional operators are expressed as Kronecker product operators:

- *Bidimensional second order derivation operators δ_x^2, δ_y^2*

$$(25) \qquad -\delta_x^2 = \frac{1}{h^2} T \otimes I, \quad -\delta_y^2 = \frac{1}{h^2} I \otimes T.$$

- *Bidimensional first order derivation operators δ_x, δ_y*

$$(26) \qquad \delta_x = \frac{1}{2h} K \otimes I, \quad \delta_y = \frac{1}{2h} I \otimes K.$$

- *Bidimensional Hermitian gradient*

$$(27) \qquad U_x = \frac{3}{h}\left[P^{-1}K \otimes I\right]U, \qquad U_y = \frac{3}{h}\left[I \otimes P^{-1}K\right]U.$$

- *Mixed derivative $\delta_x^2 \delta_y^2$*

$$(28) \qquad \delta_x^2 \delta_y^2 = \frac{1}{h^4} T \otimes T.$$

• *Fourth order derivation operators in two dimensions*

$$(29) \quad \begin{cases} \delta_x^4 = \dfrac{12}{h^2}\left[\dfrac{3}{2h^2}KP^{-1}K + \dfrac{1}{h^2}T\right] \otimes I, \\[3mm] \delta_y^4 = \dfrac{12}{h^2}I \otimes \left[\dfrac{3}{2h^2}KP^{-1}K + \dfrac{1}{h^2}T\right]. \end{cases}$$

The following summarizes several preliminary results about matrices K,P,T.

LEMMA 2.1. (i) *The commutator of P and K is*

$$(30) \qquad\qquad [P,K] = PK - KP = 2\,(E_{N-1} - E_1)\,.$$

(ii) *The commutator of P^{-1} and K is*

$$(31) \qquad [P^{-1}, K] = P^{-1}K - KP^{-1} = -2P^{-1}\big(E_{N-1} - E_1\big)P^{-1}.$$

(iii) *The symmetric matrix K^2 is related to T by*

$$(32) \qquad\qquad K^2 = T^2 - 4T + 2(E_1 + E_{N-1}).$$

Proof. (i) is easily verified, (ii) is deduced from (i) by conjugation by P^{-1}, and (iii) the following identities are simply verified:

$$(33) \quad \begin{cases} (K^2 U)_i = U_{i+2} + U_{i-2} - 2U_i, & 2 \le i \le N-2, \\ (K^2 U)_1 = U_3 - U_1, \\ (K^2 U)_{N-1} = -U_{N-1} + U_{N-3}, \end{cases}$$

$$(34) \quad \begin{cases} (T^2 U)_i = U_{i+2} - 4U_{i+1} + 6U_i - 4U_{i-1} + U_{i-2}, & 2 \le i \le N-2, \\ (T^2 U)_1 = -(TU)_2 + 2(TU)_1 = U_3 - 4U_2 + 5U_1, \\ (T^2 U)_{N-1} = U_{N-3} - 4U_{N-2} + 5U_{N-1}. \end{cases}$$

Therefore,

$$(35) \quad \begin{cases} \big((K^2 - T^2)U\big)_i = 4U_{i+1} - 8U_i + 4U_{i-1} = -4(TU)_i, & 2 \le i \le N-2, \\ \big((K^2 - T^2)U\big)_1 = -4(TU)_1 + 2U_1, \\ \big((K^2 - T^2)U\big)_{N-1} = -4(TU)_{N-1} + 2U_{N-1}, \end{cases}$$

which gives (32). □

3. A fast FFT solver for the Stephenson biharmonic.

3.1. The FFT Poisson solver. Here we recall briefly the standard FFT algorithm for the discrete Laplacian according to [6], [26]. Consider the Poisson problem in the square $\Omega = (0, L)^2$

$$(36) \qquad \begin{cases} -\Delta u(x,y) = f, & (x,y) \in \Omega = (0, L)^2, \\ u(x,y) = 0, & (x,y) \in \partial\Omega, \end{cases}$$

whose discrete form is (see (6))

$$(37) \qquad \begin{cases} -\Delta_h u_{i,j} = f_{i,j}, & 1 \le i,j \le N-1, \\ u_{i,j} = 0, & i \in \{0, N\} \text{ or } j \in \{0, N\}. \end{cases}$$

The eigenvectors of $-\delta_x^2$, which form a basis of $l_{h,0}^2$, are $z^k \in l_{h,0}^2$ defined by (L is the length of the interval),

$$(38) \qquad z_j^k = \left(\frac{2}{L}\right)^{1/2} \sin\frac{kj\pi h}{L}, \quad 1 \le k, j \le N-1.$$

They form an orthonormal basis for the one-dimensional scalar product $(.,.)_h$,

$$(39) \qquad (z^k, z^l)_h = \delta_{k,l}, \quad 1 \le k, l \le N-1.$$

Cast in vector form, we introduce the column vector $Z^k \in \mathbb{R}^{N-1}$, and row vector $Z_j \in \mathbb{R}^{N-1}$ is defined by

$$(40) \qquad Z^k = h^{1/2} z^k, \quad Z_j = h^{1/2} z_j, \quad 1 \le k, j \le N-1,$$

$$(41) \qquad Z_j^k = \left(\frac{2}{N}\right)^{1/2} \sin\frac{kj\pi}{N}, \quad 1 \le k, j \le N-1.$$

The matrix $Z \in \mathbb{M}_{N-1}(\mathbb{R})$, whose kth column is Z^k and jth row is Z_j, is a symmetric positive definite unitary matrix, thus

$$(42) \qquad Z^2 = ZZ^T = I_{N-1}.$$

The eigenvalues of the matrix T are given by (see (19))

$$(43) \qquad \lambda_k = 4\sin^2\left(\frac{k\pi}{2N}\right).$$

In matrix form, the scheme (37) reduces to the linear system with right-hand side $F = h^2 \operatorname{vect}(f) \in \mathbb{R}^{(N-1)^2}$ and unknown $U = \operatorname{vect}(u) \in \mathbb{R}^{(N-1)^2}$

$$(44) \qquad (T \otimes I + I \otimes T) U = F.$$

The orthonormal basis (in $\mathbb{R}^{(N-1)^2}$ of $T \otimes I + I \otimes T$ is $(Z^k \otimes Z^l)_{1 \le k, l \le N-1}$, with eigenvalues $(\lambda_k + \lambda_l)_{1 \le k, l \le N-1}$.

The algorithm of the fast Poisson solver is in 3 steps (see [26, 6] for more details).
ALGORITHM 1 (fast FFT Poisson solver).
- *Step* 1. Decompose the source term $F = h^2 \operatorname{vect}(f)$ on the orthonormal basis $Z^k \otimes Z^l$. This step consists of computing the coefficients $F_{k,l}^Z = (F, Z^k \otimes Z^l)$ and is performed by FFT (actually the fast *sine* transform).
- *Step* 2. Solve system (44) in the Fourier space by

$$(45) \qquad u_{k,l}^Z = \frac{F_{k,l}^Z}{\lambda_k + \lambda_l}.$$

- *Step* 3. Assemble componentwise the solution using the decomposition of the grid function $U \in \mathbb{R}^{(N-1)^2}$ in $Z^k \otimes Z^l$,

$$(46) \qquad U_{i,j} = \sum_{k,l=1}^{N-1} U_{k,l}^Z Z_i^k Z_j^l.$$

The grid function $u \in L_{h,0}^2$ is such that $U = \operatorname{vect}(u)$, therefore

$$(47) \qquad u_{i,j} = U_{i,j}, \quad 1 \le i, j \le N-1.$$

Steps 1 and 3 are $O(N^2 \operatorname{Log}(N))$, and step 2 is $O(N^2)$, which gives a $O(N^2 \operatorname{Log}(N))$ algorithm. For the complexity analysis of the FFT, we refer to [36] and [23].

3.2. The Stephenson operator. Let us begin by representing the finite difference operator δ_x^4 (8) in matrix form.

LEMMA 3.1. *The operator $P\delta_x^4 u$ has the following matrix form:*

$$(48) \qquad P\delta_x^4 = \frac{6}{h^4}T^2 + \frac{36}{h^4}\left[e_1(e_1 + KP^{-1}e_1)^T + e_{N-1}(e_{N-1} - KP^{-1}e_{N-1})^T\right].$$

Observe that $P\delta_x^4 u$ is not symmetric.

Proof. We use systematically that for all column vectors $u, v \in \mathbb{R}^{N-1}$, then $u^T, v^T \in \mathbb{R}^{N-1}$ are row vectors. For A a $(N-1) \times (N-1)$ matrix, the following relation holds:

$$(49) \qquad u(v^T A) = (uv^T)A = u(A^T v)^T.$$

The finite difference operator δ_x^4 reads in matrix form (see (22))

$$(50) \qquad \delta_x^4 = \frac{6}{h^4}\left[3KP^{-1}K + 2T\right].$$

Multiplying on the left by P gives, using (30),

$$P\delta_x^4 = \frac{6}{h^4}[3PKP^{-1}K + 2PT]$$
$$= \frac{6}{h^4}[3[P,K]P^{-1}K + 3KPP^{-1}K + 2PT]$$
$$= \frac{6}{h^4}[6(E_{N-1} - E_1)P^{-1}K + 3K^2 + 2(6I - T)T].$$

Using the expression of K^2 as a function of T (see (32)) and $(P^{-1})^T = P^{-1}$, $K^T = -K$,

$$P\delta_x^4 = \frac{6}{h^4}[6e_{N-1}e_{N-1}^T P^{-1}K - 6e_1 e_1^T P^{-1}K$$
$$+ 3(T^2 - 4T + 2e_1 e_1^T + 2e_{N-1}e_{N-1}^T) + 12T - 2T^2]$$
$$= \frac{6}{h^4}[-6e_{N-1}e_{N-1}^T (P^{-1})^T K^T + 6e_1 e_1^T (P^{-1})^T K^T + T^2 + 6e_1 e_1^T + 6e_{N-1}e_{N-1}^T]$$
$$= \frac{6}{h^4}T^2 + \frac{36}{h^4}[e_1(e_1 + KP^{-1}e_1)^T + e_{N-1}(e_{N-1} - KP^{-1}e_{N-1})^T],$$

which is the result. ∎

LEMMA 3.2. *The symmetric positive definite operator δ_x^4 (see (22)) has the alternative matrix form*

$$(51) \qquad \delta_x^4 = \frac{6}{h^4}P^{-1}T^2 + \frac{36}{h^4}\left(v_1 v_1^T + v_2 v_2^T\right),$$

where the vectors v_1, v_2 are

$$(52) \qquad \begin{cases} v_1 = (\alpha - \beta)^{1/2}P^{-1}\left[\dfrac{\sqrt{2}}{2}e_1 - \dfrac{\sqrt{2}}{2}e_{N-1}\right], \\[3mm] v_2 = (\alpha + \beta)^{1/2}P^{-1}\left[\dfrac{\sqrt{2}}{2}e_1 + \dfrac{\sqrt{2}}{2}e_{N-1}\right]. \end{cases}$$

The matrix P is given in (14), and the constants α, β are

(53)
$$\begin{cases} \alpha = 2(2 - e_1^T P^{-1} e_1), \\ \beta = 2 e_{N-1}^T P^{-1} e_1. \end{cases}$$

Proof. Applying P^{-1} to both sides of (48), we obtain

$$\begin{aligned} \delta_x^4 &= P^{-1}(P\delta_x^4) \\ &= \frac{6}{h^4} P^{-1} T^2 + \frac{36}{h^4} \left\{ P^{-1} e_1 (e_1 + KP^{-1} e_1)^T + P^{-1} e_{N-1}(e_{N-1} - KP^{-1} e_{N-1})^T \right\}. \end{aligned}$$

Therefore, the term in braces, referred to as (I),

(54) $(I) = P^{-1} e_1 (e_1 + KP^{-1} e_1)^T + P^{-1} e_{N-1}(e_{N-1} - KP^{-1} e_{N-1})^T$

is expanded as

$$\begin{aligned} (I) &= P^{-1} e_1 e_1^T - P^{-1} e_1 e_1^T P^{-1} K + P^{-1} e_{N-1} e_{N-1}^T + P^{-1} e_{N-1} e_{N-1}^T P^{-1} K \\ &= P^{-1} e_1 e_1^T - P^{-1} e_1 e_1^T K P^{-1} + P^{-1} e_1 e_1^T [K, P^{-1}] + P^{-1} e_{N-1} e_{N-1}^T \\ &\quad + P^{-1} e_{N-1} e_{N-1}^T K P^{-1} + P^{-1} e_{N-1} e_{N-1}^T [P^{-1}, K]. \end{aligned}$$

Using the value of the commutator (31),

$$[K, P^{-1}] = -2P^{-1}(E_1 - E_{N-1})P^{-1} = -2P^{-1}\left(e_1 e_1^T - e_{N-1} e_{N-1}^T\right)P^{-1} = -[P^{-1}, K].$$

We then obtain that (I) is the conjugate of (II) by P^{-1}, i.e.,

(55) $(I) = P^{-1}(II)P^{-1},$

with (II) defined as

$$\begin{aligned} (II) &= e_1 e_1^T P - e_1 e_1^T K - 2 e_1 e_1^T P^{-1} e_1 e_1^T + 2 e_1 e_1^T P^{-1} e_{N-1} e_{N-1}^T \\ &\quad + e_{N-1} e_{N-1}^T P + e_{N-1} e_{N-1}^T K + 2 e_{N-1} e_{N-1}^T P^{-1} e_1 e_1^T \\ &\quad - 2 e_{N-1} e_{N-1}^T P^{-1} e_{N-1} e_{N-1}^T. \end{aligned}$$

Therefore, (I) rewrites

(56) $(I) = P^{-1}\{(S) + (S')\}P^{-1},$

where (S) and (S') are the matrices defined by

$$\begin{aligned} (S) &= -2 e_1 e_1^T P^{-1} e_1 e_1^T - 2 e_{N-1} e_{N-1}^T P^{-1} e_{N-1} e_{N-1}^T \\ &\quad + 2\left(e_1 e_1^T P^{-1} e_{N-1} e_{N-1}^T + e_{N-1} e_{N-1}^T P^{-1} e_1 e_1^T\right) \\ (S') &= e_1[(P+K)e_1]^T + e_{N-1}[(P-K)e_{N-1}]^T. \end{aligned}$$

The matrix (S) is clearly symmetric. In addition, we verify easily that

(57) $\begin{cases} (P+K)e_1 = 4e_1, \\ (P-K)e_{N-1} = 4e_{N-1}. \end{cases}$

Therefore, the matrix (S') reduces to

(58) $(S') = 4 e_1 e_1^T + 4 e_{N-1} e_{N-1}^T$

and is as well symmetric. We deduce from (56) that (I) can be written as

$$(I) = P^{-1}\big[-2e_1e_1^T P^{-1}e_1e_1^T - 2e_{N-1}e_{N-1}^T P^{-1}e_{N-1}e_{N-1}^T$$
$$+ 2e_1e_1^T P^{-1}e_{N-1}e_{N-1}^T + 2e_{N-1}e_{N-1}^T P^{-1}e_1e_1^T + 4e_1e_1^T + 4e_{N-1}e_{N-1}^T \big] P^{-1},$$

or

(59)
$$(I) = P^{-1}\Big[e_1, e_{N-1} \Big] \begin{bmatrix} \alpha & \beta \\ \beta & \alpha \end{bmatrix} \begin{bmatrix} e_1^T \\ e_{N-1}^T \end{bmatrix} P^{-1},$$

with

(60)
$$\begin{cases} \alpha = 4 - 2e_1^T P^{-1}e_1 = 4 - 2e_{N-1}^T P^{-1}e_{N-1}, \\ \beta = 2e_1^T P^{-1}e_{N-1} = 2e_{N-1}^T P^{-1}e_1. \end{cases}$$

Using, in (59), that

(61)
$$\begin{bmatrix} \alpha & \beta \\ \beta & \alpha \end{bmatrix} = \begin{bmatrix} \dfrac{\sqrt{2}}{2} & \dfrac{\sqrt{2}}{2} \\ -\dfrac{\sqrt{2}}{2} & \dfrac{\sqrt{2}}{2} \end{bmatrix} \begin{bmatrix} \alpha - \beta & 0 \\ 0 & \alpha + \beta \end{bmatrix} \begin{bmatrix} \dfrac{\sqrt{2}}{2} & -\dfrac{\sqrt{2}}{2} \\ \dfrac{\sqrt{2}}{2} & \dfrac{\sqrt{2}}{2} \end{bmatrix},$$

we obtain that (I) is the symmetric matrix

(62)
$$(I) = \Big[v_1, v_2 \Big] \begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix},$$

where the vectors v_1, v_2 are

(63)
$$\begin{cases} v_1 = (\alpha - \beta)^{1/2} P^{-1}\left(\dfrac{\sqrt{2}}{2}e_1 - \dfrac{\sqrt{2}}{2}e_{N-1} \right), \\ v_2 = (\alpha + \beta)^{1/2} P^{-1}\left(\dfrac{\sqrt{2}}{2}e_1 + \dfrac{\sqrt{2}}{2}e_{N-1} \right), \end{cases}$$

which gives (51). ∎

Cast in the matrix framework, formula (51) is a decomposition of the one-dimensional Stephenson biharmonic operator δ_x^4 in two parts,

(64)
$$A = h^4 \delta_x^4 = \underbrace{6P^{-1}T^2}_{B} + \underbrace{36[v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix}}_{C}.$$

We note that $B \in \mathrm{Span}(T)$, since $P = 6I - T$ and that C is a rank 2 matrix. We can therefore use the *Sherman–Morrison* formula.

FORMULA 3.1 (Sherman–Morrison [18, Chapter 2, p. 50]). *Suppose that* $A, B \in \mathbb{M}_N(\mathbb{R})$ *are two invertible matrices such that*

(65)
$$A = B + RS^T,$$

with $R, S \in \mathbb{M}_{N,n}(\mathbb{R})$, $n \le N$; *then the inverse of the matrix* A *can be written as*

(66)
$$A^{-1} = B^{-1} - B^{-1}R(I + S^T B^{-1}R)^{-1}S^T B^{-1},$$

provided that the matrix $I + S^T B^{-1}R \in \mathbb{M}_n(\mathbb{R})$ *be invertible.*

When $n \ll N$, the matrix A is a low-rank perturbation of the matrix B. Hence, in the case that B is easily invertible, (66) provides an efficient way to invert A. In the following section, (66) is used to solve the biharmonic problem in a rectangle.

3.3. Solution procedure. We now turn to the study of the discrete differential operators in the two-dimensional setting.

PROPOSITION 3.3. *The Stephenson discrete biharmonic operator* Δ_h^2 *can be expressed as (see the remark after* (22)*)*

$$(67) \qquad \Delta_h^2 = \frac{1}{h^4}[6P^{-1}T^2 \otimes I_{N-1} + 6I \otimes P^{-1}T^2 + 2T \otimes T]$$

$$+ \frac{36}{h^4}[v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes I_{N-1} + \frac{36}{h^4}I_{N-1} \otimes [v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix}.$$

Proof. This is a simple consequence of the definition (7) of Δ_h^2 and of (29), (51). Recall that x-operators act as left factors in Kronecker products and y-factors operate as right factors. The term $2T \otimes T$ corresponds to the mixed derivative $\delta_x^2\delta_y^2$. ∎

We decompose now the bidimensional discrete operator $h^4\Delta_h^2$ according to (67) to a diagonal part (with respect to the basis $Z^k \otimes Z^l$, (38)), and a perturbation part, which will turn out to be lower dimensional. We therefore write

$$(68) \qquad \mathcal{A} = \mathcal{B} + \mathcal{C},$$

where the matrices $\mathcal{A}, \mathcal{B}, \mathcal{C}$ are specified as follows:
- $\mathcal{A}$ is the matrix corresponding to $h^4\Delta_h^2$ in (67).
- $\mathcal{B}$ is the $(N-1)^2 \times (N-1)^2$ matrix

  $$(69) \qquad \mathcal{B} = 6P^{-1}T^2 \otimes I_{N-1} + 6I_{N-1} \otimes P^{-1}T^2 + 2T \otimes T.$$

  $\mathcal{B}$ is diagonal in the basis $Z^k \otimes Z^l$ and will be referred to for convenience as the "diagonal" part of matrix $\mathcal{A}$.
- $\mathcal{C}$ is the $(N-1)^2 \times (N-1)^2$ matrix (see (63) for the definition of v_1, v_2),

  $$(70) \qquad \mathcal{C} = 36\left([v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes I_{N-1} + I_{N-1} \otimes [v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix}\right).$$

Denoting by Z^k, Z_l, respectively, the column and line vectors of the unitary matrix (40), we replace in (70) the identity matrix I_{N-1} by

$$(71) \qquad I_{N-1} = ZZ^T = \left[Z^1, Z^2, \ldots, Z^{N-1}\right]\begin{bmatrix} Z_1 \\ . \\ . \\ . \\ Z_{N-1} \end{bmatrix}.$$

The interest of the decomposition of the identity operator (71), instead of the trivial one, will appear in the resolution of the capacitance system; see the appendix.

The matrix in braces in (70) is therefore

$$\underbrace{[v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes \left[Z^1, Z^2, \ldots, Z^{N-1}\right]\begin{bmatrix} Z_1 \\ . \\ . \\ . \\ Z_{N-1} \end{bmatrix}}_{(a)}$$

$$(72) \qquad + \underbrace{\left[Z^1, Z^2, \ldots, Z^{N-1}\right]\begin{bmatrix} Z_1 \\ . \\ . \\ . \\ Z_{N-1} \end{bmatrix} \otimes [v_1, v_2]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix}}_{(b)}.$$

At this point we use several rules of the Kronecker product algebra (see [36]), namely, the following:
(i) For all matrices A, B, C, D,

$$(73) \qquad (A \otimes B)(C \otimes D) = (AC) \otimes (BD)$$

assuming that the ordinary products AC and BD are defined.
(ii) For all matrices A, B,

$$(74) \qquad (A \otimes B)^T = A^T \otimes B^T.$$

Applying (73), (74), and the definition of the Kronecker product (12), the term (a) in (72) can be rewritten as

$$(a) = \left([v_1, v_2] \otimes [Z^1, Z^2, \ldots, Z^{N-1}] \right) \left(\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes \begin{bmatrix} Z_1 \\ \cdot \\ \cdot \\ Z_{N-1} \end{bmatrix} \right)$$

$$= \begin{bmatrix} v_1 \otimes Z^1, \ldots, v_1 \otimes Z^{N-1} \end{bmatrix} \begin{bmatrix} v_1^T \otimes Z_1 \\ \cdot \\ \cdot \\ v_1^T \otimes Z_{N-1} \end{bmatrix}$$

$$+ \begin{bmatrix} v_2 \otimes Z^1, \ldots, v_2 \otimes Z^{N-1} \end{bmatrix} \begin{bmatrix} v_2^T \otimes Z_1 \\ \cdot \\ \cdot \\ v_2 \otimes Z_{N-1} \end{bmatrix}.$$

Combining this with similar calculations applied to term (b) in (72), it turns out that the matrix $\mathcal{C}$ in (70) can be expressed as a low-rank $(N-1)^2 \times (N-1)^2$ matrix in the form

$$(75) \qquad \mathcal{C} = 36 \mathcal{R} \mathcal{R}^T,$$

where $\mathcal{R}$ is a matrix $(N-1)^2 \times 4(N-1)$, written in the form

$$(76) \qquad \mathcal{R} = [R_1, R_2, R_3, R_4].$$

In what follows, we refer to $\mathcal{C}$ as the "perturbation" (or *capacitance*) part of $\bar{A}$.
The four $(N-1)^2 \times (N-1)$ matrices R_k are

$$(77) \qquad \begin{cases} R_1 = [v_1 \otimes Z^1, v_1 \otimes Z^2, \ldots, v_1 \otimes Z^{N-1}], \\ R_2 = [v_2 \otimes Z^1, v_2 \otimes Z^2, \ldots, v_2 \otimes Z^{N-1}], \\ R_3 = [Z^1 \otimes v_1, Z^2 \otimes v_1, \ldots, Z^{N-1} \otimes v_1], \\ R_4 = [Z^1 \otimes v_2, Z^2 \otimes v_2, \ldots, Z^{N-1} \otimes v_2]. \end{cases}$$

The interest of this decomposition (instead of the one using the canonical factorization of the identity operator) will appear clearly in the appendix. Applying the Sherman–Morrison formula to the matrix

$$(78) \qquad \mathcal{A} = \mathcal{B} + 36 \mathcal{R} \mathcal{R}^T$$

allows us to express $\mathcal{A}^{-1}$ as

$$(79) \qquad \mathcal{A}^{-1} = \mathcal{B}^{-1} - 36 \mathcal{B}^{-1} \mathcal{R} [I_{4(N-1)} + 36 \mathcal{R}^T \mathcal{B}^{-1} \mathcal{R}]^{-1} \mathcal{R}^T \mathcal{B}^{-1}.$$

We use now (79) to solve the system

$$(80) \qquad \mathcal{A}U = F$$

with $\mathcal{A} = h^4 \Delta_h^2$, $F = h^4 \operatorname{vect}(f)$.

The following algorithm summarizes the solution procedure according to formula (66). Indications of the computing complexity are given at each step of the algorithm.

ALGORITHM 2 (fast FFT algorithm for the biharmonic problem).

- *Step* 1. *Solve* $\mathcal{B}g = F$. Let $F \in \mathbb{R}^{(N-1)^2}$ be the source-term vector $F = h^4 \operatorname{vect}(f)$. The linear system for $g \in \mathbb{R}^{(N-1)^2}$

$$(81) \qquad \mathcal{B}g = F$$

  is solved using the FFT as follows. First, F is decomposed on the basis $Z^k \otimes Z^l$ where the vector Z^k, $k = 1, \ldots, N - 1$, are the eigenfunctions (40) of matrix T, as

$$(82) \qquad F = \sum_{k,l=1}^{N-1} F_{k,l}^Z Z^k \otimes Z^l,$$

  where the coefficients $F_{k,l}^Z$ are

$$(83) \qquad F_{k,l}^Z = (F, Z^k \otimes Z^l), \quad 1 \le k, l \le N - 1.$$

  Equation (83) is computed by FFT. The eigenvalues of $\mathcal{B}$ are

$$(84) \qquad \mu_{k,l} = \frac{\lambda_k^2}{(1 - \lambda_k/6)} + \frac{\lambda_l^2}{(1 - \lambda_l/6)} + 2\lambda_k \lambda_l,$$

  and $g = \mathcal{B}^{-1} F$ is given by

$$(85) \qquad g = \sum_{k,l=1}^{N-1} \frac{F_{k,l}^Z}{\mu_{k,l}} Z^k \otimes Z^l.$$

  The vector $g \in \mathbb{R}^{(N-1)^2}$ is stored for step 7. The FFT computation (83) is $O(N^2 \operatorname{Log}(N))$ and (85) is $O(N^2)$.

- *Step* 2. Compute the vector $\mathcal{R}^T g \in \mathbb{R}^{4(N-1)}$,

$$(86) \qquad \mathcal{R}^T g = \begin{bmatrix} R_1^T g \\ R_2^T g \\ R_3^T g \\ R_4^T g \end{bmatrix}.$$

  We have, for example,

$$(87) \qquad R_1^T g = \begin{bmatrix} (v_1 \otimes Z^1)^T g \\ . \\ . \\ (v_1 \otimes Z^{N-1})^T g \end{bmatrix}.$$

The l-component of vector $R_1^T g$ in (87) is

$$(88) \qquad (v_1 \otimes Z^l)^T g = \sum_{i=1}^{N-1} (v_1)_i \sum_{j=1}^{N-1} g_{i,j} Z_l^j.$$

Each term

$$(89) \qquad \sum_{j=1}^{N-1} g_{i,j} Z_l^j, \quad 1 \le i \le N-1,$$

is computed by FFT (actually the fast sine transform) via

$$(90) \qquad \sum_{j=1}^{N-1} g_{i,j} Z_l^j = \left(\frac{2}{N}\right)^{1/2} \sum_{j=1}^{N-1} g_{i,j} \sin \frac{lj\pi}{N}.$$

Similarly, the kth component in $R_3^T g$ is

$$(91) \qquad (R_3^T g)_k = (Z^k \otimes v_1)^T g = \sum_{j=1}^{N-1} (v_1)_j \sum_{i=1}^{N-1} g_{i,j} Z_k^i.$$

The FFT is used to compute

$$(92) \qquad \sum_{i=1}^{N-1} g_{i,j} Z_k^i = \left(\frac{2}{N}\right)^{1/2} \sum_{i=1}^{N-1} g_{i,j} \sin \frac{ik\pi}{N}.$$

The expressions of $R_2^T g$ and $R_4^T g$ are similar, replacing v_1 by v_2. As for the counting complexity of step 2, (89) is $O(N \log(N))$ for each value of i, which gives $O(N^2 \log(N))$ in all. Then (87) is $O(N^2)$ using (88). The same is true for each of the four components of $\mathcal{R}^T g$ in (86).

- *Step* 3. Assemble the $4(N-1) \times 4(N-1)$ capacitance matrix in brackets in formula (79)

$$(93) \qquad I_{4(N-1)} + 36 \mathcal{R}^T \mathcal{B}^{-1} \mathcal{R}.$$

We refer to the appendix for the detailed structure of the symmetric matrix (93), as well as for the $O(N^2)$ computing complexity of its assembling. Note that matrix (93) is computed once for all.

- *Step* 4. Solve the $4(N-1) \times 4(N-1)$ linear system

$$(94) \qquad \left(I_{4(N-1)} + 36 \mathcal{R}^T \mathcal{B}^{-1} \mathcal{R} \right) s = \mathcal{R}^T g.$$

The computing complexity of the whole algorithm relies on the efficiency of this solving. It is performed by the preconditioned conjugate gradient method. Numerical evidence displays a $O(N^2 \log(N))$ computing cost; we refer to the appendix for more details. The solution $s \in \mathbb{R}^{4(N-1)}$ is decomposed in

$$(95) \qquad s = [s_1, s_2, s_3, s_4]^T, \quad s_1, s_2, s_3, s_4 \in \mathbb{R}^{N-1}.$$

- *Step* 5. Perform the product of $t = \mathcal{R}s$, $s \in \mathbb{R}^{4(N-1)}$, $t \in \mathbb{R}^{(N-1)^2}$;

$$(96) \qquad\qquad t = t_1 + t_2 + t_3 + t_4,$$

with

$$(97) \qquad \begin{cases} t_1 = \left(v_1 \otimes [Z^1, \dots, Z^{N-1}]\right) s_1, \\[2mm] t_2 = \left(v_2 \otimes [Z^1, \dots, Z^{N-1}]\right) s_2, \\[2mm] t_3 = \left([Z^1, \dots, Z^{N-1}] \otimes v_1\right) s_3, \\[2mm] t_4 = \left([Z^1, \dots, Z^{N-1}] \otimes v_2\right) s_4. \end{cases}$$

For $1 \le i, j \le N-1$,

$$(98) \qquad \begin{cases} (t_1)_{i,j} = (v_1)_i \sum_{l=1}^{N-1} (s_1)_l Z_j^l, \\[2mm] (t_2)_{i,j} = (v_2)_i \sum_{l=1}^{N-1} (s_2)_l Z_j^l, \\[2mm] (t_3)_{i,j} = (v_1)_j \sum_{k=1}^{N-1} (s_3)_k Z_i^k, \\[2mm] (t_4)_{i,j} = (v_2)_j \sum_{k=1}^{N-1} (s_4)_k Z_i^k. \end{cases}$$

Each sum in each right-hand side in (98) is computed by *FFT*, which gives a cost of $O(N \operatorname{Log}(N))$. The computation of the vector $t \in \mathbb{R}^{(N-1)^2}$ in (96) is therefore $O(N^2 \operatorname{Log}(N))$.

- *Step* 6. Resolution of the linear system in $\mathbb{R}^{(N-1)^2}$

$$(99) \qquad\qquad v = \mathcal{B}^{-1} t$$

via the fast FFT solver as in step 1. The cost is $O(N^2 \operatorname{Log}(N))$.

- *Step* 7. Assemble the solution $\psi \in \mathbb{R}^{(N-1)^2} \overset{\text{vect}}{\simeq} L_{h,0}^2$ of the biharmonic problem (5) (with $(a,b) = (0,1)$) by

$$(100) \qquad\qquad \psi = g - 36v,$$

where $g, v \in \mathbb{R}^{(N-1)^2}$ are given in (85), (99). The cost is $O(N^2)$.

- *Step* 8. Compute the Hermitian gradient $\psi_x, \psi_y \in \mathbb{R}^{(N-1)^2}$ as a postprocessing of the grid values of ψ by

$$(101) \qquad \begin{cases} \psi_x = \left(\dfrac{3}{h} P^{-1} K \otimes I\right) \psi, \\[3mm] \psi_y = \left(\dfrac{3}{h} I \otimes P^{-1} K\right) \psi. \end{cases}$$

Computation (101) is performed using the one-dimensional FFT for a global cost $O(N^2 \operatorname{Log}(N))$.

The overall computing cost of Algorithm 2 is therefore $O(N^2)\,\mathrm{Log}(N)$ under the assumption that step 4 is at most $O(N^2\,\mathrm{Log}(N))$; see the appendix. Let us conclude this section by considering now the case of problem (4) discretized by (5), with $a \geq 0, b > 0$. The matrix form of the finite difference operator $-a\Delta_h + b\Delta_h^2$ is

$$(102) \qquad -a\Delta_h + b\Delta_h^2 = \frac{a}{h^2}\left[T \otimes I + I \otimes T\right] + \frac{b}{h^4}\left(\mathcal{B} + \mathcal{C}\right).$$

Defining

$$(103) \qquad \mathcal{B}^{a,b} = ah^2\left[T \otimes I + I \otimes T\right] + b\mathcal{B},$$

we have

$$(104) \qquad h^4(-a\Delta_h + b\Delta_h^2) = \mathcal{B}^{a,b} + b\mathcal{C}.$$

It turns out that the algorithm that solves problem (5) is now exactly the same as Algorithm 2, replacing the eigenvalues $\mu_{k,l}$ of $\mathcal{B}$ by

$$(105) \qquad \mu_{k,l}^{a,b} = ah^2(\lambda_k + \lambda_l) + b\left(\frac{\lambda_k^2}{(1 - \lambda_k/6)} + \frac{\lambda_l^2}{(1 - \lambda_l/6)} + 2\lambda_k\lambda_l\right).$$

In addition $\mathcal{C}$ is replaced by $b\mathcal{C}$ in (75), (79).

3.4. Treatment of nonhomogeneous boundary conditions. Let us first consider the modifications of $\delta_x^4 u$ at near-boundary points. We write

$$(106) \qquad \delta_x^4 u = \frac{12}{h^2}(\delta_x u_x - \delta_x^2 u).$$

Let U be a one-dimensional vector of length $N - 1$, associated with the values of the solution u for a fixed y. The vector U_x is associated with the approximated derivative of u. At near-boundary points $x = x_1$ we have

$$(107) \qquad (\delta_x u_x)_{x=x_1} = \frac{1}{2h}((U_x)_2 - (U_x)_0).$$

Similarly, for $x = x_{N-1}$

$$(108) \qquad (\delta_x u_x)_{x=x_{N-1}} = \frac{1}{2h}((U_x)_N - (U_x)_{N-2}).$$

Therefore, we can write

$$(109) \qquad \delta_x u_x = \frac{1}{2h}KU_x + \frac{1}{2h}\begin{bmatrix} -(U_x)_0 \\ . \\ . \\ (U_x)_N \end{bmatrix}.$$

We replace KU_x by $KP^{-1}PU_x$ and get

$$(110) \qquad \delta_x u_x = \frac{1}{2h}KP^{-1}PU_x + \frac{1}{2h}\begin{bmatrix} -(U_x)_0 \\ . \\ . \\ (U_x)_N \end{bmatrix}.$$

Now, for $i = 1, \ldots, N-1$ we have $(U_x)_{i+1} + 4(U_x)_i + (U_x)_{i-1} = \frac{6}{2h}(U_{i+1} - U_{i-1})$. For $i = 1$ we have

$$(111) \qquad (U_x)_2 + 4(U_x)_1 = \frac{6}{2h}U_2 - \frac{6}{2h}U_0 - (U_x)_0.$$

Similarly, for $i = N-1$,

$$(112) \qquad 4(U_x)_{N-1} + (U_x)_{N-2} = -\frac{6}{2h}U_{N-2} + \frac{6}{2h}U_N - (U_x)_N.$$

Thus, it follows that

$$(113) \qquad PU_x = \frac{6}{2h}KU.$$

For $i = 1$ we have

$$(114) \qquad (U_x)_2 + 4(U_x)_1 = \frac{6}{2h}U_2 - \frac{6}{2h}U_0 - (U_x)_0.$$

Similarly, for $i = N-1$

$$(115) \qquad 4(U_x)_{N-1} + (U_x)_{N-2} = -\frac{6}{2h}U_{N-2} + \frac{6}{2h}U_N - (U_x)_N.$$

Thus, it follows that

$$(116) \qquad PU_x = \frac{6}{2h}KU + \begin{bmatrix} -\frac{6}{2h}U_0 - (U_x)_0 \\ . \\ . \\ \frac{6}{2h}U_N - (U_x)_N \end{bmatrix}.$$

Therefore,

$$(117) \quad \delta_x u_x = \frac{3}{2h^2}KP^{-1}KU + \frac{1}{2h}KP^{-1}\begin{bmatrix} -\frac{6}{2h}U_0 - (U_x)_0 \\ 0 \\ . \\ . \\ 0 \\ \frac{6}{2h}U_N - (U_x)_N \end{bmatrix} + \frac{1}{2h}\begin{bmatrix} -(U_x)_0 \\ 0 \\ . \\ . \\ 0 \\ (U_x)_N \end{bmatrix}.$$

We also have that

$$(118) \qquad (\delta_x^2 u)_{x=x_1} = \frac{1}{h^2}(U_2 - 2U_1 + U_0).$$

Similarly, for $x = x_{N-1}$

$$(119) \qquad (\delta_x^2 u)_{x=x_1} = \frac{1}{h^2}(U_N - 2U_{N-1} + U_{N-2}).$$

Thus,

$$(120) \qquad \delta_x^2 u = -\frac{T}{h^2}U + \frac{1}{h^2}\begin{bmatrix} U_0 \\ . \\ . \\ U_N \end{bmatrix}.$$

Therefore,

$$\delta_x^4 u = \frac{12}{h^2} \left(\left[\frac{3}{2h^2} KP^{-1}K + \frac{1}{h^2}T \right] U + \frac{1}{2h} KP^{-1} \begin{bmatrix} -\frac{6}{2h}U_0 - (U_x)_0 \\ 0 \\ . \\ . \\ 0 \\ \frac{6}{2h}U_N - (U_x)_N \end{bmatrix} \right.$$

(121)
$$\left. + \frac{1}{2h} \begin{bmatrix} -(U_x)_0 \\ 0 \\ . \\ . \\ 0 \\ (U_x)_N \end{bmatrix} - \frac{1}{h^2} \begin{bmatrix} U_0 \\ 0 \\ . \\ . \\ 0 \\ U_N \end{bmatrix} \right).$$

Note that the previous expression is a perturbation of the operator δ_x^4 that we received in (22), where the additional terms come from the boundary. Since the value of the solution, along with its first order derivatives, is known on the boundary, they may be transformed to the right-hand side of the equation.

$\delta_y^4 u$ may be expressed in a similar way. The mixed derivative $\delta_x^2 \delta_y^2 u$ yields modifications involving the values of U only at the boundary.

4. A fourth order compact scheme for biharmonic problems.

4.1. Fourth order accurate nine-point compact schemes. In this subsection, we describe how to modify the nine-point biharmonic operator (7) and the five-point Laplacian (6) in order to obtain fourth order accuracy.

The one-dimensional operators $\delta_x^4 \psi_{i,j}$, $\delta_y^4 \psi_{i,j}$ in (122) are given as functions of ψ, ψ_x, ψ_y by

(122) $\qquad \delta_x^4 \psi_{i,j} = \frac{12}{h^2} [(\delta_x \psi_x)_{i,j} - (\delta_x^2 \psi)_{i,j}], \quad \delta_y^4 \psi_{i,j} = \frac{12}{h^2} [(\delta_y \psi_y)_{i,j} - (\delta_y^2 \psi)_{i,j}].$

These two operators are fourth order accurate (see [3]). The second order accuracy of the operator Δ_h^2 is due only to the term $\delta_x^2 \delta_y^2 \psi_{i,j}$. Thus, the local truncation error is $\delta_x^2 \delta_y^2 \psi_{i,j} - \partial_x^2 \partial_y^2 \psi_{i,j} = O(h^2)$. The latter may be checked using Taylor expansion of ψ around (x_i, y_j), or by checking the truncation error in $\delta_x^2 \delta_y^2 \psi_{i,j}$ by applying it to a Fourier mode $\psi = e^{i(kx+ly)}$. We refer to [3] for the study of the accuracy at near-boundary points.

In order to derive a fourth order approximation to $\partial_x^2 \psi$ we proceed as follows. The Taylor expansion of $\delta_x^2 \psi$, $\delta_x \psi_x$ is

(123) $$\delta_x^2 \psi_i = \partial_x^2 \psi_i + \frac{h^2}{12} \partial_x^4 \psi_i + O(h^4),$$

(124) $$\delta_x \psi_{x,i} = \partial_x^2 \psi_i + \frac{h^2}{6} \partial_x^4 \psi_i + O(h^4).$$

A linear combination of these two operators allows us to derive the fourth order accurate approximation $\tilde{\delta}_x^2$ to $\partial_x^2 \psi$, eliminating the h^2 term in the following way:

(125) $$\tilde{\delta}_x^2 \psi_i = 2\delta_x^2 \psi_i - \delta_x \psi_{x,i} = \partial_x^2 \psi_i + O(h^4).$$

In a similar way we derive a fourth order accurate scheme for $\partial_y^2 \psi$, i.e.,

$$(126) \qquad \tilde{\delta}_y^2 \psi_i = 2\delta_y^2 \psi_i - \delta_y \psi_{y,i} = \partial_y^2 \psi_i + O(h^4).$$

Therefore, a fourth order approximation for the Laplacian is

$$(127) \qquad \tilde{\Delta}_h \psi_{i,j} = 2\delta_x^2 \psi_{i,j} - \delta_x \psi_{x,i,j} + 2\delta_y^2 \psi_{i,j} - \delta_y \psi_{y,i,j}.$$

Invoking

$$(128) \qquad \delta_x \psi_x - \delta_x^2 \psi = \frac{h^2}{12}\delta_x^4 \psi, \quad \delta_y \psi_y - \delta_y^2 \psi = \frac{h^2}{12}\delta_y^4 \psi,$$

and applying it to (127), we find that the operator $\tilde{\Delta}_h$ may be rewritten as a perturbation of Δ_h in the following way:

$$(129) \qquad \tilde{\Delta}_h = \delta_x^2 - \frac{h^2}{12}\delta_x^4 + \delta_y^2 - \frac{h^2}{12}\delta_y^4 = \Delta_h - \frac{h^2}{12}(\delta_x^4 + \delta_y^4).$$

In a similar manner we construct a fourth order accurate approximation to $\partial_x^2 \partial_y^2 \psi_{i,j}$. First, we expand $\delta_y^2 \delta_x \psi$ in powers of h

$$(130)$$
$$\delta_y^2 \delta_x \psi_{x,i,j} = \partial_y^2\left[\partial_x^2 \psi_{i,j} + \frac{h^2}{6}\partial_x^4 \psi_{i,j} + O(h^4)\right] + \frac{h^2}{12}\partial_y^4\left[\partial_x^2 \psi_{i,j} + \frac{h^2}{6}\partial_x^4 \psi_{i,j} + O(h^4)\right] + O(h^4).$$

Thus,

$$(131) \qquad \delta_y^2 \delta_x \psi_{x,i,j} = \partial_x^2 \partial_y^2 \psi_{i,j} + \frac{h^2}{6}\partial_y^2 \partial_x^4 \psi_{i,j} + \frac{h^2}{12}\partial_y^4 \partial_x^2 \psi_{i,j} + O(h^4).$$

Symmetrically,

$$(132) \qquad \delta_x^2 \delta_y \psi_{y,i,j} = \partial_x^2 \partial_y^2 \psi_{i,j} + \frac{h^2}{6}\partial_x^2 \partial_y^4 \psi_{i,j} + \frac{h^2}{12}\partial_x^4 \partial_y^2 \psi_{i,j} + O(h^4).$$

The Taylor expansion of the mixed operator $\delta_x^2 \delta_y^2$ is therefore

$$(133) \qquad \delta_x^2 \delta_y^2 \psi_{i,j} = \partial_x^2 \partial_y^2 \psi_{i,j} + \frac{h^2}{12}\partial_x^2 \partial_y^4 \psi_{i,j} + \frac{h^2}{12}\partial_y^2 \partial_x^4 \psi_{i,j} + O(h^4).$$

Combining (133), (132), (130), we define the new mixed finite-difference operator $\widetilde{\delta_x^2 \delta_y^2} \psi_{i,j}$ as

$$(134) \qquad \widetilde{\delta_x^2 \delta_y^2} \psi_{i,j} = 3\delta_x^2 \delta_y^2 \psi_{i,j} - \delta_x^2 \delta_y \psi_{y,i,j} - \delta_y^2 \delta_x \psi_{x,i,j} = \partial_x^2 \partial_y^2 \psi_{i,j} + O(h^4).$$

Keeping δ_x^4 and δ_y^4 as before, we define the fourth order biharmonic operator $\tilde{\Delta}_h^2$ as

$$(135) \qquad \tilde{\Delta}_h^2 \psi_{i,j} = \delta_x^4 \psi_{i,j} + \delta_y^4 \psi_{i,j} + 2\widetilde{\delta_x^2 \delta_y^2} \psi_{i,j}.$$

Invoking (128) again allows us to rewrite the fourth order operator $\tilde{\Delta}_h^2$ as a perturbation of Δ_h^2 in the following way:

$$(136) \qquad \tilde{\Delta}_h^2 = \delta_x^4\left(I - \frac{h^2}{6}\delta_y^2\right) + \delta_y^4\left(I - \frac{h^2}{6}\delta_x^2\right) + 2\delta_x^2 \delta_y^2.$$

Finally, the new fourth order scheme which approximates (4) is

(137)
$$\begin{cases} \big[-a\tilde{\Delta}_h + b\tilde{\Delta}_h^2\big]\psi_{i,j} = f_{i,j}, & 1 \le i,j \le N-1, \\ \psi_{i,j} = 0, \quad \psi_{x,i,j} = \psi_{y,i,j} = 0, & i \in \{0,N\}, j \in \{0,N\}. \end{cases}$$

As a consequence of (136), a fourth order approximation to the biharmonic equation $\Delta^2\psi = f$ is

(138)
$$\tilde{\Delta}_h^2 = \delta_x^4\left(I - \frac{h^2}{6}\delta_y^2\right) + \delta_y^4\left(I - \frac{h^2}{6}\delta_x^2\right) + 2\delta_x^2\delta_y^2 = f.$$

Note that in the right-hand side of (138) only the value of $f(i,j)$ is involved in the discretization of the differential equation at (x_i, y_j). This feature of the scheme is important in cases where the biharmonic problem has to be solved when the function f is unknown on the boundary, but is known only at interior points (see [3]). A different fourth order accurate scheme for the biharmonic equation $\Delta^2\psi = f$ was presented in [33, section 3.2] and a multigrid solver was designed for this scheme in [1]. The scheme in [33, section 3.2] involves the five values of f, $f_{i,j}, f_{i+1,j}, f_{i-1,j}, f_{i,j+1}$, and $f_{i,j-1}$, in order to construct a fourth order approximation to the biharmonic operator.

Note, finally, that in (138) the gradient (ψ_x, ψ_y) is used at all nine points of the stencil of the scheme. In a forthcoming paper, an analogous scheme for irregular domains will be derived, using directional derivatives at corner points.

4.2. Fast solution procedure. The fast solution procedure for solving (136) follows exactly the same lines as in section 3. The matrix forms of the positive operators $\tilde{\Delta}_h^2$ and $-(\tilde{\Delta}_h)$ are

$$\begin{cases} \tilde{\Delta}_h^2 &= \frac{1}{h^4}\big(6P^{-1}T^2 \otimes \big(I_{N-1} + \frac{T}{6}\big) + 6\big(I_{N-1} + \frac{T}{6}\big) \otimes P^{-1}T^2 + 2T \otimes T\big) \\ &+ \frac{36}{h^4}\big[v_1, v_2\big]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes \big(I_{N-1} + \frac{T}{6}\big) + \frac{36}{h^4}\big(I_{N-1} + \frac{T}{6}\big) \otimes \big[v_1, v_2\big]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \\ -(\tilde{\Delta}_h) &= \frac{1}{h^2}\big(T \otimes I + I \otimes T + \frac{1}{2}[P^{-1}T^2 \otimes I_{N-1} + I_{N-1} \otimes P^{-1}T^2]\big) \\ &+ \frac{3}{h^2}\big[v_1, v_2\big]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes I_{N-1} + \frac{3}{h^2}I_{N-1} \otimes \big[v_1, v_2\big]\begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix}. \end{cases}$$

The matrix form $\mathcal{A}'$ of the fourth order operator $h^4(-a\tilde{\Delta}_h + b\tilde{\Delta}_h^2)$ as a "diagonal" part $\mathcal{B}'$ and a "capacitance" part $\mathcal{C}'$ (see section 3.3) is

(139)
$$\mathcal{A}' = \mathcal{B}' + \mathcal{C}'$$

with

$$\mathcal{B}' = ah^2\left(T \otimes I + I \otimes T + \frac{1}{2}[P^{-1}T^2 \otimes I_{N-1} + I_{N-1} \otimes P^{-1}T^2]\right)$$
$$+ b\left(6P^{-1}T^2 \otimes \left(I_{N-1} + \frac{T}{6}\right) + 6\left(I_{N-1} + \frac{T}{6}\right) \otimes P^{-1}T^2 + 2T \otimes T\right).$$

The eigenvectors of $\mathcal{B}'$ are $Z^k \otimes Z^l$ and the eigenvalues are

$$\mu'_{k,l} = ah^2\left((\lambda_k + \lambda_l) + \frac{1}{12}\frac{\lambda_k^2}{(1 - \lambda_k/6)} + \frac{1}{12}\frac{\lambda_l^2}{(1 - \lambda_l/6)}\right)$$

$$+ b\left(\lambda_k^2\frac{1 + \lambda_l/6}{1 - \lambda_k/6} + \lambda_l^2\frac{1 + \lambda_k/6}{1 - \lambda_l/6} + 2\lambda_k\lambda_l\right).$$

The capacitance part of $\mathcal{A}'$ is

$$
\mathcal{C}' = 36 \left([v_1, v_2] \begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \otimes \left(\left(\frac{ah^2}{12} + b \right) I_{N-1} + b \frac{T}{6} \right) \right.
$$

(140)
$$
\left. + \left(\left(\frac{ah^2}{12} + b \right) I_{N-1} + b \frac{T}{6} \right) \otimes [v_1, v_2] \begin{bmatrix} v_1^T \\ v_2^T \end{bmatrix} \right).
$$

The structure of $\mathcal{C}'$ is the same as before,

(141)
$$
\mathcal{C}' = 36 \mathcal{R}' \mathcal{R}'^T,
$$

where $\mathcal{R}'$ is the $(N-1)^2 \times 4(N-1)$ matrix

(142)
$$
\mathcal{R}' = [R_1', R_2', R_3', R_4'],
$$

and

(143)
$$
\begin{cases}
R_1' = [v_1 \otimes Z'^{,1}, v_1 \otimes Z'^{,2}, \dots, v_1 \otimes Z'^{,N-1}], \\
R_2' = [v_2 \otimes Z'^{,1}, v_2 \otimes Z'^{,2}, \dots, v_2 \otimes Z'^{,N-1}], \\
R_3' = [Z'^{,1} \otimes v_1, Z'^{,2} \otimes v_1, \dots, Z'^{,N-1} \otimes v_1], \\
R_4' = [Z'^{,1} \otimes v_2, Z'^{,2} \otimes v_2, \dots, Z'^{,N-1} \otimes v_2],
\end{cases}
$$

with
(144)
$$
Z' = [Z'^{,1}, Z'^{,2}, \dots, Z'^{,N-1}], \quad Z'^{,j} = \left(\frac{ah^2}{12} + b \left(1 + \frac{\lambda_j}{6} \right) \right)^{1/2} Z^j, \quad 1 \le j \le N-1.
$$

The numerical algorithm for (137) is the same as Algorithm 2, replacing $\mathcal{B}, \mathcal{C}, \mathcal{R}, Z$ by $\mathcal{B}', \mathcal{C}', \mathcal{R}', Z'$. Nonhomogeneous boundary conditions are treated as in subsection 3.4.

5. Numerical results. The numerical results presented have been obtained with a code written in FORTRAN90. The package *fftpack* of Swarztrauber [35] has been used for computing the FFT. In addition, we have used the *g*95 compiler [37] without optimization. The computations have been run in double precision on a laptop with an Intel Pentium M 2.13 GHZ processor, with 1GB memory.

5.1. Accuracy. We report numerical results obtained so far with the two versions of the scheme, the second order and fourth order versions. The discrete L^2 and L^∞ errors are defined by

(145)
$$
\begin{cases}
(a) & \|\psi - \psi_h\|_h = \left[h^2 \sum_{i,j} (\psi(x_i, y_j) - \psi_{i,j})^2 \right]^{1/2}, \\
(c) & \|\psi - \psi_h\|_{\infty,h} = \sup_{i,j=1,\dots,N-1} |\psi(x_i, y_j) - \psi_{i,j}|.
\end{cases}
$$

Taking into account nonhomogeneous boundary conditions gives an additional contribution to the right-hand side for near boundary points, whose value is simply deduced from the boundary values of ψ, ψ_x, ψ_y on the four edges, which appear in the expression of the discrete Laplacian and biharmonic operators.

• *Example* 1. The problem solved is (5) with exact solution $\psi(x, y) = \sin^2(x) \sin^2(y)$ on the square $\Omega = [0, \pi]^2$. That test is the same as Example 2 in [1] and Example 1 in [5]. Table 1 reports the numerical results with the second order accurate scheme (5) (with $(a, b) = (0, 1)$). The source term is $\Delta^2 \psi(x, y)$ and the boundary conditions

TABLE 1

Altas et al.(N=64)[1]	0.10008	$(0.5, 0.766)$

• *Example* 3. In order to demonstrate the efficiency of the fourth order scheme (137), we present several examples of problems (4) with coefficients $(a, b) = (1, 2)$, for which we applied our fourth order scheme (137). For the first test problem

$$(147) \qquad \psi(x, y) = (1 + x^2)(1 + y^2).$$

Here we received zero error up to the machine accuracy, according to the fact that the scheme is exact for fourth order polynomials.

• *Example* 4. Consider the case where the exact solution is

$$(148) \qquad \psi(x, y) = (1 - x^2)^2(1 - y^2)^2, \quad -1 \le x, y \le 1.$$

This function solves the equation

$$-\Delta\psi + 2\Delta^2\psi = f(x, y),$$

where $f(x, y) = -\Delta\psi + 2\Delta^2\psi$ is the forcing term. In this case we have homogeneous boundary conditions.

Table 4 summarizes the errors, $e = \|\psi - \psi_h\|_h$, and the error in the x- and y-derivatives $e_x = \|\partial_x\psi - \psi_{x,h}\|_h$, $e_y = \|\partial_y\psi - \psi_{y,h}\|_h$.

N	32	Rate	64	Rate	128	Rate	256
e	$2.0763(-6)$	4.03	$1.2735(-7)$	4.00	$7.9604(-9)$	4.08	$4.9762(-10)$
e_x	$3.4466(-6)$	4.00	$2.1542(-7)$	4.00	$1.3465(-8)$	4.00	$8.4173(-10)$
e_y	$3.4466(-6)$	4.00	$2.1542(-7)$	4.00	$1.3465(-8)$	4.00	$8.4173(-10)$

• *Example* 5. An additional example with nonzero boundary conditions is

$$\psi(x, y) = (x^4 + y^4)^2.$$

The results are summarized in Table 5.

5.2. Computing efficiency. We report here the CPU time in seconds for the fourth order scheme (137) (FORTRAN90, Intel Pentium 2.13 GHZ, 1GB memory). In Table 6 we display the CPU time for some of the results in Table 2. CPU$_{tot}$ stands for the time which corresponds to obtain the complete solution of the linear system,

TABLE 5

Error and convergence rates in $\|.\|_h$ norm for $\psi(x, y) = (x^4 + y^4)^2$, $(a, b) = (1, 2)$ with the fourth order scheme (137).

N	32	Rate	64	Rate	128	Rate	256

while CPU_∞ stands for the CPU time for the solution procedure without assembling the capacitance matrix (93) (step 3 of Algorithm 2). Note that the capacitance matrix does not depend on the right-hand side of the system of equations; thus for a time-dependent problem it may be computed only once. In Table 6 we also report on the ratio $\text{CPU}_{tot} / (N^2 \, \text{Log}(N))$. It seems from the computations that this ratio is slowly decreasing to a constant. In addition, we report on the number of iterations in the conjugate gradient (CG) algorithm for the capacitance linear system to converge within a prescribed accuracy of 10^{-20}. We refer the reader to the appendix for some estimates on the condition number of the capacitance matrix. It can be observed in Table 6 that the number of iterations in the CG algorithm grow very slowly. In practice, we observe that the spectral part of the solution procedure is more demanding in computing resources compared to the capacitance matrix solving part.

TABLE 6

Indicative CPU time for results in Table 2.

N	$N=64$	$N=128$	$N=256$	$N=512$	$N=1024$	$N=2048$
CPU_{tot}	0.016s	0.11s	0.47s	1.91s	7.67s	33.52s
CPU_∞	0.016s	0.093s	0.38s	1.52s	6.28s	27.28s

k_{CG}	17	18	19	19	21	23

In Table 7 we report on the computing efficiency, as well as the number of CG iterations, of our solver for a nonseparable biharmonic problem in $\Omega = [0, 1]^2$, [1], with exact solution

(149) $$\psi(x, y) = x^3 \ln(1 + y) + \frac{y}{1 + x}.$$

Observe that, for this example too, the number of iterations in the CG algorithm grow very slowly.

6. Conclusion. The capacitance matrix method, applied to the second order Stephenson scheme (10) and to the fourth order scheme (137), appears to be efficient; this seems to be competitive with the multigrid method reported by Altas et al. [1]. In the latter the solver is designed for the fourth order Stephenson scheme and

the numerical results are limited to 128×128 grids. In addition, the design of our algorithm seems to be simpler than the fast solver presented in [5] for the OSC scheme.

In fact, we currently use the new algorithm to solve the time-dependent Navier–Stokes equation on fine grids. Finally, note that the extension of the solution procedure to problems with boundary condition on $\Delta \psi$ can be handled without major modifications, which can be carried out using the discretizations (6) or (127). In addition, the extension to three-dimensional problems appears to be tractable by a similar procedure.

Appendix. Resolution of the capacitance linear system. Here we focus on the resolution of the capacitance system (94). Consider first the $4(N-1) \times 4(N-1)$ matrix $\mathcal{R}\mathcal{B}^{-1}\mathcal{R}^T$, which has a 4×4 block structure,

$$
(150) \qquad \mathcal{R}^T \mathcal{B}^{-1} \mathcal{R} = \begin{bmatrix} R_1^T \mathcal{B}^{-1} R_1 & R_1^T \mathcal{B}^{-1} R_2 & R_1^T \mathcal{B}^{-1} R_3 & R_1^T \mathcal{B}^{-1} R_4 \\ R_2^T \mathcal{B}^{-1} R_1 & R_2^T \mathcal{B}^{-1} R_2 & R_2^T \mathcal{B}^{-1} R_3 & R_2^T \mathcal{B}^{-1} R_4 \\ R_3^T \mathcal{B}^{-1} R_1 & R_3^T \mathcal{B}^{-1} R_2 & R_3^T \mathcal{B}^{-1} R_3 & R_3^T \mathcal{B}^{-1} R_4 \\ R_4^T \mathcal{B}^{-1} R_1 & R_4^T \mathcal{B}^{-1} R_2 & R_4^T \mathcal{B}^{-1} R_3 & R_4^T \mathcal{B}^{-1} R_4 \end{bmatrix},
$$

where the four $(N-1)^2 \times (N-1)$ matrices R_k are given in (77). By symmetry, only the upper diagonal part of (150) has to be computed. The vector $Z^j \in \mathbb{R}^{N-1}$ is given in (41) and the vectors $v_1, v_2 \in \mathbb{R}^{N-1}$ in (63) are decomposed as a linear combination of Z^k by

$$
(151) \qquad \begin{cases} v_1 = (\alpha - \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k - Z_{N-1}^k}{6 - \lambda_k} Z^k, \\[4mm] v_2 = (\alpha + \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k + Z_{N-1}^k}{6 - \lambda_k} Z^k. \end{cases}
$$

Therefore for $i = 1, \ldots, N-1$,

$$
(152) \qquad \begin{cases} \text{(i)} \quad v_1 \otimes Z^i = (\alpha - \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k - Z_{N-1}^k}{6 - \lambda_k} Z^k \otimes Z^i, \\[4mm] \text{(ii)} \quad v_2 \otimes Z^i = (\alpha + \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k + Z_{N-1}^k}{6 - \lambda_k} Z^k \otimes Z^i, \\[4mm] \text{(iii)} \quad Z^i \otimes v_1 = (\alpha - \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k - Z_{N-1}^k}{6 - \lambda_k} Z^i \otimes Z^k, \\[4mm] \text{(iv)} \quad Z^i \otimes v_2 = (\alpha + \beta)^{1/2} \dfrac{\sqrt{2}}{2} \displaystyle\sum_{k=1}^{N-1} \dfrac{Z_1^k + Z_{N-1}^k}{6 - \lambda_k} Z^i \otimes Z^k. \end{cases}
$$

Operating with $\mathcal{B}^{-1}$ on the left in $(152)_{i,ii,iii,iv}$ gives, for $j = 1, \ldots, N-1$,

$$(153) \quad \begin{cases} \text{(i)} \quad \mathcal{B}^{-1}(v_1 \otimes Z^j) = (\alpha - \beta)^{1/2} \frac{\sqrt{2}}{2} \sum_{k=1}^{N-1} \frac{Z_1^k - Z_{N-1}^k}{(6 - \lambda_k)\mu_{k,j}} Z^k \otimes Z^j, \\[2mm] \text{(ii)} \quad \mathcal{B}^{-1}(v_2 \otimes Z^j) = (\alpha + \beta)^{1/2} \frac{\sqrt{2}}{2} \sum_{k=1}^{N-1} \frac{Z_1^k + Z_{N-1}^k}{(6 - \lambda_k)\mu_{k,j}} Z^k \otimes Z^j, \\[2mm] \text{(iii)} \quad \mathcal{B}^{-1}(Z^j \otimes v_1) = (\alpha - \beta)^{1/2} \frac{\sqrt{2}}{2} \sum_{k=1}^{N-1} \frac{Z_1^k - Z_{N-1}^k}{(6 - \lambda_k)\mu_{k,j}} Z^k \otimes Z^j, \\[2mm] \text{(iv)} \quad \mathcal{B}^{-1}(Z^j \otimes v_2) = (\alpha + \beta)^{1/2} \frac{\sqrt{2}}{2} \sum_{k=1}^{N-1} \frac{Z_1^k + Z_{N-1}^k}{(6 - \lambda_k)\mu_{k,j}} Z^k \otimes Z^j. \end{cases}$$

Taking the $\mathbb{R}^{(N-1)^2}$ scalar product of (152) and (153), and using that

$$(154) \quad \left(Z^k \otimes Z^l, Z^{k'} \otimes Z^{l'} \right) = \delta_{k,k'} \delta_{l,l'}, \quad 1 \le k, k', l, l' \le N-1,$$

yields that the term (i, j) of the matrix $R_1^T \mathcal{B}^{-1} R_1$ is

$$(155) \quad (v_1 \otimes Z^i)^T \mathcal{B}^{-1}(v_1 \otimes Z^j) = \frac{\alpha - \beta}{2} \delta_{i,j} \sum_{k=1}^{N-1} \left(\frac{Z_1^k - Z_{N-1}^k}{6 - \lambda_k} \right)^2 \frac{1}{\mu_{k,j}}.$$

This proves that the $(N-1) \times (N-1)$ matrix $D_1 = R_1^T \mathcal{B}^{-1} R_1$ is actually diagonal. Using

$$(156) \quad Z_{N-1}^k = \left(\frac{2}{N} \right)^{1/2} \sin \frac{k(N-1)\pi}{N} = (-1)^{k+1} \left(\frac{2}{N} \right)^{1/2} \sin \frac{k\pi}{N} = (-1)^{k+1} Z_1^k$$

in (155) yields that the diagonal coefficient $(D_1)_j$ is

$$(157) \quad \left[R_1^T \mathcal{B}^{-1} R_1 \right]_{j,j} = \frac{4(\alpha - \beta)}{N} \sum_{k=1,k \text{ even}}^{N-1} \sin^2 \left(\frac{k\pi}{N} \right) \frac{1}{(6 - \lambda_k)^2 \mu_{k,j}}.$$

Similarly, we find that the matrix $D_2 = R_2^T \mathcal{B}^{-1} R_2$ is diagonal as well, with jth coefficient

$$(v_2 \otimes Z^j)^T \mathcal{B}^{-1}(v_2 \otimes Z^j) = \frac{1}{2}(\alpha + \beta) \sum_{k=1}^{N-1} \left(\frac{Z_1^k + Z_{N-1}^k}{6 - \lambda_k} \right)^2 \frac{1}{\mu_{k,j}}$$

$$= \frac{4(\alpha + \beta)}{N} \sum_{k=1,k \text{ odd}}^{N-1} \sin^2 \left(\frac{k\pi}{N} \right) \frac{1}{(6 - \lambda_k)^2 \mu_{k,j}}.$$

In addition, using that $\mu_{k,l} = \mu_{l,k}$ it is easy to verify that

$$(158) \quad \begin{cases} R_3^T \mathcal{B}^{-1} R_3 = R_1^T \mathcal{B}^{-1} R_1, \\[2mm] R_4^T \mathcal{B}^{-1} R_4 = R_2^T \mathcal{B}^{-1} R_2, \end{cases}$$

and that

$$
(159) \qquad
\begin{cases}
R_1^T \mathcal{B}^{-1} R_2 = 0, \\
R_3^T \mathcal{B}^{-1} R_4 = 0.
\end{cases}
$$

Finally, we obtain that the matrices $M_{1,3} = R_1^T \mathcal{B}^{-1} R_3$, $M_{1,4} = R_1^T \mathcal{B}^{-1} R_4$, $M_{2,4} = R_2^T \mathcal{B}^{-1} R_4$ are given by

$$
(160) \qquad (R_1^T \mathcal{B}^{-1} R_3)_{i,j} =
\begin{cases}
\dfrac{4(\alpha - \beta)}{N} \dfrac{\sin \frac{i\pi}{N} \sin \frac{j\pi}{N}}{(6 - \lambda_i)(6 - \lambda_j)\mu_{i,j}} & \text{if } i \text{ even}, \ j \text{ even} \\
0 \quad \text{if } i \text{ odd or } j \text{ odd},
\end{cases}
$$

$$
(161)
$$
$$
(R_1^T \mathcal{B}^{-1} R_4)_{i,j} =
\begin{cases}
\dfrac{4(\alpha - \beta)^{1/2}(\alpha + \beta)^{1/2}}{N} \dfrac{\sin \frac{i\pi}{N} \sin \frac{j\pi}{N}}{(6 - \lambda_i)(6 - \lambda_j)\mu_{i,j}} & \text{if } i \text{ odd}, \ j \text{ even} \\
0 \quad \text{if } i \text{ even or } j \text{ odd},
\end{cases}
$$

$$
(162)
$$
$$
(R_2^T \mathcal{B}^{-1} R_3)_{i,j} =
\begin{cases}
\dfrac{4(\alpha - \beta)^{1/2}(\alpha + \beta)^{1/2}}{N} \dfrac{\sin \frac{i\pi}{N} \sin \frac{j\pi}{N}}{(6 - \lambda_i)(6 - \lambda_j)\mu_{i,j}} & \text{if } i \text{ even}, \ j \text{ odd} \\
0 \quad \text{if } i \text{ odd or } j \text{ even},
\end{cases}
$$

$$
(163) \qquad (R_2^T \mathcal{B}^{-1} R_4)_{i,j} =
\begin{cases}
\dfrac{4(\alpha + \beta)}{N} \dfrac{\sin \frac{i\pi}{N} \sin \frac{j\pi}{N}}{(6 - \lambda_i)(6 - \lambda_j)\mu_{i,j}} & \text{if } i \text{ odd}, \ j \text{ odd} \\
0 \quad \text{if } i \text{ even or } j \text{ even}.
\end{cases}
$$

Using that

$$
(164) \qquad (R_1^T \mathcal{B}^{-1} R_4)^T = (R_2^T \mathcal{B}^{-1} R_3),
$$

it results that the $4(N-1) \times 4(N-1)$ matrix $\mathcal{R}^T \mathcal{B}^{-1} \mathcal{R}$ has the 4×4 block structure

$$
(165) \qquad
\mathcal{R}^T \mathcal{B}^{-1} \mathcal{R} =
\begin{bmatrix}
D_1 & 0 & M_{1,3} & M_{1,4} \\
0 & D_2 & M_{1,4}^T & M_{2,4} \\
M_{1,3} & M_{1,4} & D_1 & 0 \\
M_{1,4}^T & M_{2,4} & 0 & D_2
\end{bmatrix}.
$$

Formulas (157), (160), (161), (162), and (163) show that the computing cost for the assembling is $O(N^2)$. The capacitance matrix $I + 36\mathcal{R}^T \mathcal{B}^{-1} \mathcal{R}$ in (94) is therefore

$$
(166) \qquad
I + 36\mathcal{R}^T \mathcal{B}^{-1} \mathcal{R} =
\begin{bmatrix}
I + 36D_1 & 0 & 36M_{1,3} & 36M_{1,4} \\
0 & I + 36D_2 & 36M_{1,4}^T & 36M_{2,4} \\
36M_{1,3} & 36M_{1,4} & I + 36D_1 & 0 \\
36M_{1,4}^T & 36M_{2,4} & 0 & I + 36D_2
\end{bmatrix}.
$$

This symmetric positive matrix has the form $I_{4(N-1)} + \tilde{Z}^T \tilde{Z} \geq I$, where

$$
(167) \qquad \tilde{Z} = 6(\mathcal{B}^{-1})^{1/2} \mathcal{R}.
$$
FIG. 1. *Curve* $\mathrm{Log}_2(N) \mapsto \sigma_{\max}(\bar{M})$.

The conjugate gradient method can be applied to (94). The simple diagonal preconditioning yields a linear system $\mathcal{M}g = g'$ with a matrix of the form

$$(168) \qquad \mathcal{M} = \begin{bmatrix} I_{2(N-1)} & \bar{M} \\ \bar{M}^T & I_{2(N-1)} \end{bmatrix},$$

where $\bar{M} \in \mathbb{M}_{2(N-1)}(\mathbb{R})$ is defined by

$$(169) \qquad \bar{M} = \begin{bmatrix} (\frac{1}{36}I + D_1)^{-1}M_{13} & (\frac{1}{36}I + D_1)^{-1}M_{14} \\ (\frac{1}{36}I + D_2)^{-1}M_{14}^T & (\frac{1}{36}I + D_2)^{-1}M_{24} \end{bmatrix}.$$

Solving (94) with the CG method for the matrix in (168) has been proved to be very efficient. Equivalently, one can split the linear system into two independent linear systems of size $2(N-1)$ and matrices $I_{2(N-1)} - \bar{M}^T\bar{M}$ and $I_{2(N-1)} - \bar{M}\bar{M}^T$ [10], each of them being solved by the CG algorithm.

The convergence analysis of the CG algorithm (see, for example, [13, Chapter 8, p. 249]) yields that the norm of the error is reduced by a factor ε after k iterations. Here k is selected such that

$$(170) \qquad k \geq \frac{1}{2}\sqrt{\kappa_2(I - \bar{M}\bar{M}^T)}\ln(2/\varepsilon),$$

where $\kappa_2(I - \bar{M}\bar{M}^T)$ is the condition number of $I - \bar{M}\bar{M}^T$.

The eigenvalues of $I - \bar{M}\bar{M}^T$ are

$$(171) \qquad 0 < \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_{2(N-1)} \leq 1,$$

where $\lambda_k = 1 - \sigma_k^2$ and σ_k is the kth singular value of $\bar{M}$. Therefore,

$$(172) \qquad \kappa_2(I - \bar{M}\bar{M}^T) \leq \frac{1}{1 - \sigma_{\max}^2(\bar{M})}.$$

A full analytic estimate of $\sigma_{\max}(\bar{M})$ seems to be difficult to derive. Thus, we limit ourselves to the numerical study of the relation between $\mathrm{Log}_2(N)$ and $\sigma_{\max}(\bar{M})$. In Figure 1 we display the graph of $\mathrm{Log}_2(N) \mapsto \sigma_{\max}(\bar{M})$. Here N is the size of the

problem, which ranges from 2 to 2600. This value encompasses the number of grid points, which is usually picked for two-dimensional problems. As can be observed in Figure 1, one can infer a monotonic increase in the behavior of $\sigma_{\max}(\bar{M})$ as a function of N, with a very slow growth for large N. The existence of a bound uniform in N, though very plausible, is not completely apparent. Anyway, we observe numerically that $\sigma_{max}(N) \leq 0.7$ for $N \leq 2600$. For a given tolerance error ε, the lower bound for the number of iterations k is independent in practice of the grid size, namely, $k \geq 0.7 \ln(2/\varepsilon)$, at least for $N \leq 2600$ (see (170)). Since each iteration of the CG algorithm is $O(N^2)$, we have that step 4 in Algorithm 2 is in practice $O(N^2)$. In Tables 6 and 7 we report on the number of iterations of the CG algorithm for the system (94) for the two specific examples. It indicates a very slow increasing behavior of the number of iterations of the CG algorithm, corroborating Figure 1.
